 Agricultural Society in Botany Bay, notice of 21—of Essex, statement of premiums offered by 43—of South Carolina, notice of their choosing a committee to import foreign seeds, &c. 51—of Cheshire, N. H., notice of their celebration 90—of Middlesex, officers of 95, premiums awarded by 219—of Hillsborough, report of 91, 100—of Massachusetts, notice of their premiums 34—notice of their celebration 76, 94, 102—reports of Committees of 97, 98, 99, 105, 106, 170—of Rhode Island, account of their proceedings 106, of Hartford, Conn. account of their cattle show 106, of their proceedings 360—of Worcester, account of their cattle show 100, reports of 154, 165, 173, 189, 191, 196, 187—of Berkshire, notice of their exhibition 101—of Bristol, County 114—of Hancock, Me. 124—of Nova Scotia 136—of Rockingham, N. H., report of the committee of 138—of Cheshire, N. H., premiums of 219—of Rhode Island, report of 225—of Hartford, Conn. proceedings of 260—of Worcester County, officers of 323, report of a committee relative to admitting the clergymen of the County, *ex officio* as members 323—of Essex, their notice to farmers respecting viewing farms 406.
 Agricultural Establishment at Merchant's Row, Boston, remarks on 334.
 Agricultural Institution contemplated at Derby, Conn. notice of 302.

- Agriculture of Nova Scotia, notice of improvements in 357, 361.
 Agricultural books, for sale by the principal booksellers in Boston, a list of 196, 206.
 Albanian A. his observations on joining the waters of the Hudson river with those of the Lakes 96.
 Alch Isaac, Esq. statement of his manner of making compost manure 293.
 Alkaline solution, a patent obtained for, to render cloth incombustible, and protect timber from rotting, &c. 239.
 Allen, Rev. Wilkes, his remarks on preserving cider in bottles 394.
 Almond, remarks on its cultivation in the U. S. 157.
 Analysis of soils would be useful to agriculturists 20—modes of 68—of the bucklands in Penn. by R. H. Rose, Esq. 20.
 Anderson Mr. his remarks on making cheese 342.
 Apple jelly, process of making 37.
 Apples, notice of several very large 127—how preserved in glazed jars 67.
 Aphid, a sort of louse which injures fruit trees, notice of 402.
 Aqueduct pipes, manufactured in Concord, Mass. notice of 150.
 Arabian colt, imported by Lieut. Parker, notice of 355.
 Arable lands, how prevented from washing by, &c. 314.
 Ashes leached, valuable as a manure 322, 329.
 Aunt Betty, her observations respecting the best food for young turkeys, and remedy for gaps in 378.

B.

- B. a bad farmer, notice of his managing his farm 11—a writer with that signature, his remarks on marble trees &c. 281—recommends Geological and Agricultural Surveys 321—inquiries of respecting leached ashes as manure 322.
 Bacon and smoked beef may be preserved by dipping in ley of wood ashes 5—may be preserved by packing in oats 365.
 Balaam of Gilead, how obtained 323.
 Barley, great crop of, raised by John Watson Jun. 261.
 Barometers, cheap mode of manufacturing 262.
 Bartlett Benjamin notice of a crop of corn raised by, amounting to 174 bushels on an acre 119.
 Barton, Wm M. Esq. his Address delivered before the Agricultural Society of Winchester Virginia 156.
 Bates Isaac C. Esq. extracts from his address to the Hampshire, Franklin and Hampden Agricultural Society 202, 211.
 Bathing, cold and warm, a treatise on, by Dr. Coffin notice of 31.
 Baylies, Hon. Mr. extracts from his Address to the Bristol County Agricultural Society 148.
 Beans, transplanting of, forwards them with respect to time, but shortens the height of the stem 257.
 Bed bugs, killed or driven away by a decoction of red-pepper 344.
 Bedsteads, improved mode of constructing by Mr. Adams 277.
 Beef, on the preservation of, 153—Mr. Cooper's mode of preserving in summer 153—and Pork 163, see further Meat.
 Beer, maple receipt for making 211—spruce, receipt for 257—molasses beer receipt for, 267—hop beer receipt for making 278.
 Beet, a blood, weighing 25 pounds 802. 115.
 Beet, the sugar, notice of, raised by Mr. Prince 134—method of raising of any shape you wish 242—notice of large ones 115 119.
 Bers, a swarm of, which yielded 165 weight of honey 87—observations on 110—may be preserved in winter by removing them into a cellar 110—how hives for should be situated 134—how fed in winter 134—how their honey may be taken without destroying the insects 197—remarks on the best mode of feeding 278—remedies against the stings of, 347.
 Bene plant, from Africa, description of, and its cultivation recommended by Dr. James Smith 397.
 Beverage, for a weak constitution 110.
 Binot, an impiement for cultivating land used in Flanders 121.
 Birds eye maple, recommended as an article for cabinet furniture 67.
 Bird-shooting, the practice of condemned 301 317.
 Blacking, liquid for boots and shoes, receipt for 124.
 Black lead, for cleaning stoves best preparation for, 229.
 Blanchard Wm. Jun. his essay on cultivating hops 52.
 Bleaching linen, improvement in 49.
 Blight in pear trees, remarks on 42.
 Blodget Joseph B. large crop of flax raised by 309.
 Board fence, made crooked, and the posts not inserted in the ground, remarks on by a writer in the Vermont Republican 20—danger of its being overturned by wind, as stated by Mr. Jarvis 190—See further Fence.
 Bog, or Swamp, may be a mine of manure 18.
 Bog meadow, how improved by Jotham Jacob 197.
 Boilers, for melting fat, so constructed as to prevent offensive effluvia 51.
 Boiling, remarks on 141, 148.
 Book binders paste, how made 219.
 Bonnets, grass, observations on 341—see further Straw Bonnets.
 Books, on Agriculture to be found in the principal bookstores in Boston list of 193 266.
 Borer a worm that attacks fruit trees, remarks on 241 241—quers respecting 370.
 Botanic Garden, notice of plants presented to, by George Brown Esq. 62.
 Botts in horses, cured by drenching the horse in warm blood 84—said to be prevented by giving horses salt 291—receipt for, by W. D. Taylor Esq. 315—fish brine recommended for by E. H. Cummins 317.
 Bread, made in France by a mixture of apples and flour &c. 395.
 Brevard, John F. his notice of a disease in horses, called the "Big Head," and the mode of curing that disorder 338.
 Bridges, remarks on the preservation of, by John Kendrick Esq. 254.
 Bristol, R. his remarks on moulding earth round the top of the trunk of fruit trees to protect them from caterpillars 290.
 Broiling, remarks on 329.
 Brookline, communication from respecting lightning rods 94.
 Brown, notice of his invention for producing power 204.
 Brown, George Esq. notice of plants presented by, to the Botanic Garden 62.
 Brown, a helle, a singular character, notice of 192.
 Budding fruit trees, remarks on by Mr. C. Harrison 253—the common mode of performing 266.
 Buel Mr. his communications on grasses 161, 174—his

- estimate of the expense and profits of cultivating an acre of sand loan under two different courses of crops 177—his remarks on salt as a manure 25—his notice of the seasons 371—asserts that lime prevents the fly as well as smut in wheat 371—his remarks on seeds 269.
- Bull called the Admiral, notice of his importation 31— a Herfordshire and heifer presented to the Mass. Agricultural Society 402.
- Bunn's famous by Mrs. G., how made 59.
- Burning the moss of a swamp or bog sometimes expedient, and how effected, 16.
- Burnt Earth, for manure, on the value of and different modes of preparing, &c. 346, 372.
- Burrall, Thomas D. Esq. notice of his premium Clover Seed Machine, 368.
- Burroughs, Edward, Esq. extracts from his essays on practical Husbandry 346.
- Butcher's meat, market for in Ghent, how kept clean and neat 108.
- Butter, the best made from the strippings of the cow 81—Mr. Van Emburg's mode of making 134—remarks on the making of, in winter 150—how to take the taste of turnips from 259—bad, how cured 325—observations on the best mode of making and packing 341—badly made, which would sell for nothing, anecdote of, 397—directions for making 409.
- Butter boxes for transporting butter with ice to market, notice of 371.
- Butterfield Mr. his remarks on feeding sheep with fish and on threshing floors 205.
- C.
- Cabbages, notice of large ones, raised on Mr. C. Russell's farm, New Bedford 127—how to raise early in the Spring 112.
- Cacao American, notice of establishment, for manufacturing 5—160.
- Calf, an extraordinary one, owned by Simeon Draper Esq. 12.
- Cakes, how to make them lie quiet by balls of flour and gin, 81—to prevent their scoring 81—uncommonly large exhibited by Mr. Waring 119—mode of using adopted by the religious Society, usually called Shakers 305.
- Calico Grand, in New York, notice of, from London 49.
- Callocks, improvement in, 179.
- Can navigation, the tread-wheel applied to, 21.
- Candied Myrtle, or Bayberry shrub, remarks on its growth and uses of, 263.
- Cane sugar, remarkable instance of, 6.
- Canker worm, remedies against, 281.
- Cannon Joseph, W. his remarks on the Moon's influence on vegetation 361.
- Cannons, his communication relative to instinct, or natural affection in a young hen 205.
- Cannosha W. his remarks relative to lice on apple trees 345.
- Carp, mode of avoiding accidents in getting out 347.
- Carriage goats, observations respecting, by Hon. John Elliot 228.
- Carpenter, best destroyed with the thumb and finger 336—cannot be destroyed by a cloud of earth rolled round the top of the trunk 337—cannot be destroyed by boring a hole in trees and inserting mistone 370, 377—destroyed by collecting them in soil 412.
- Cattle, the proper time for them to breed 81—notice a malady affecting in Talbot County Virginia—remarks on foddering of 129, 130, 131, 137, lions breeds of, remarks on 210—improved Durham short horns, Col. Powell's remarks on 269—Mr. Jones's remarks on fattening with linseed oil 397—ones imported and presented by Admiral Coffin.
- Cattle Show, at Brighton, premiums offered for 74, and regulations to be observed at 75, observations on 86, account of 94, 102; agricultural products exhibited at 94; Middlesex, held at Concord, Mass. account of 92; at Hartford, Conn. notice of 83; in Ireland, N. H. 84; Report of Committees of 91, 100; Lehigh Agricultural Society in Westmoreland of Worcester, 100; of Berkshire 101; of Hartford, Conn. 106; of the Rhode Island Soc. for the Engagement of Domestic Industry 114; of the Bristol County Agricultural Society 114; in Hancock, Me. 124; in Northampton 130.
- Cedar, remarks on the durability of, 253.
- Cellars, and vaults, so constructed in Germany, that a canal or passage is opened from into the principal chimney 258.
- Cement for mending glass & china 262—one which is said to be fire proof and water proof 270.
- Champagne, a substitute for, in the juice of unripe gooseberries & sugar 123.
- Chandler Seth, his observations relative to the rot in sheep &c. 305.
- Cheese, Choptarg, very fine flavoured, notice of 27.
- Cheese, directions for making 341, 350—sometimes rendered poisonous by being covered with lead 349, 369.
- Chemistry, observations on its importance as connected with Agriculture 349.
- Chester Dr. his Address to the Albany County Agricultural Society 273.
- Chesnut tree bark, contains much of the tanning, principle and colouring matter 111.
- Cherry wine, red or black, easy method of making 27.
- Children's food, lime water recommended to use with while cutting teeth 91.
- Chimney, how constructed to carry smoke, from Professor Day's Lectures 66—how built to prevent smoking 363.
- Chickens, hatched by steam in London 304.
- Chill blains, remedy for, 211.
- Chrysalization of water, remarks on 224.
- Cider, apples for making should be well ripened 66—should be made in cool weather, and the wind from the west or North west 66—should not be pressed from the pomace, sooner than 10 or 12 hours after the apples are ground 66—an essay on making and preserving 73 89—best made from that fruit, which sinks deepest in water 73—the worse the apples for the table, the better for 73—apples for, should be spread for the purpose of sweating 73—windfalls should be made into an inferior kind of 73—mill and other implements for, should be perfectly sweet and clean 73—apples for, should be ground as fine as possible 73—the first and last running from the press should be kept by itself 73—different kinds of fermentation in 73—carbonic acid gas in should be retained as much as possible 73, 81—excessive fermentation of, how prevented 73—carbonic acid gas expelled by the acetous fermentation of, 89—advantage of a slow fermentation in 89—cider spirit may be mixed with, when fresh from the press, without the trouble of stumming with brimstone &c. 89—quantity of spirit to be mixed with, dependent on the strength of the must 89; may be strengthened and prevented from fermenting to excess by sweet substances 89—hops, elder-berries, ginger, spices &c. recommended in 89—better made into vinegar than doctored too much 89—vessels for, may be made of barrel-boards, straight, but tapering 89—beer vessels bad for, 89—how casks may be cleansed for, 89—mode of stumming casks for, 89—a solution of isinglass used to promote fermentation in, 121—better preserved with cider brandy than with Cogniac Brandy 204—how preserved in bottles, by Rev. Wilkes Allen 394.
- Circulation of sap in vegetables, Mr. Knights theory of 92.
- Cleaning silks, woollens & cottons, method of 131.
- Clergymen, Report of the committee of the Worcester Agricultural Society relative to their not being admitted *ex officio* Members of said Society 303.

- Floating First Mills, on the Ohio notice of 86.
- Flour of hard and soft wheat, should be mixed to make bread 28.
- Flowers, fragrance of preserves against insects 28.
- Fly water, a composition for killing flies 347.
- Fodder, on the advantage of using cut-straw, hay &c. 126.
- Foddering Cattle, should not commence till really necessary 129—the meaneast fodder should not be dealt out first 129—cattle which chew the cud should not be foddered after each other 130—movable rack for, how fixed 130—straw fresh threshed, best for 130—should occasionally be sprinkled with salt 130—cattle should be well foddered when young 130—barn yard should be well provided with water 137—potatoes useful for 137. See further, potatoes—cattle should be well foddered in the fore part of winter 137.
- Forbes, Alpheus, his statement of his manner of cultivating an acre of English mowing 293.
- Fowls, direction for fattening of by R. Weston 18—die on board of ships for want of sharp cornered gravel 187—gapes in, how cured 334.
- Fox, anecdote, shewing the sagacity of 261.
- Fragrance of flowers destructive to minute insects 28.
- Fruit, remarks on the stealing of, by John Landmark 34—new varieties of, presented to Massachusetts Agricultural Society by Thos. A. Knight, Esq. 91—how raised by Mr. Vaus Mons, a Dutch horticulturist 103—how preserved without sugar by Thomas Saddington 113—how preserved with honey and spring water 123—most healthy when eaten before dinner 324.
- Fruit trees, the advantage of planting on side hills 76—on girdling the branches of to force them to produce fruit 92, 93—mode adopted by Mr. Knight to hasten the bearing of 93—remarks on heading down, transplanting, &c. 221—when transplanted, the roots should not be broken, nor too much lessened in number 221—the best kinds of should be cultivated 245—Mr. Willis' wash for 277—the setting out of recommended 282—remarks on manuring by fastening putrescent substances on the bark or limbs of 290—on moulding clods of earth round the tops of their trunks 200—white wash not injurious to 326, 336.
- Frying, in cooking, directions concerning 321.
- Fuel, economy of from Parker's Chemical Essays 33.
- Fulton, his remarks on a Gas and Steam Engine 30.
- G.**
- Galvanism, remarks on experiments made with on body of John Johnson 299.
- Gaillard, J. D., his remarks on feeding stock, &c. 76.
- Gapes, a disease in hens, remedy for 331.
- Gardner A., his remarks on preserving vines from insects by gypsum powdered 361.
- Gardner, R. H. Esq. his remarks on the cultivation of wheat 53.
- Gardner Lyceum, Address of Trustees of 172—marks on 182—notice of the classes and studies: the Institution 371.
- Gas, streets in London lighted with 155—may be obtained from cotton seed 337.
- Gases, remarks on the condensation of into liquids 3.
- Gates, Ebenezer, receives a premium of \$20 from Massachusetts Agricultural Society for raising bushels of rye from 1 acre and 130 rods of gro 171.
- Geese, directions for fattening with malt, &c. 1 wild, may be tamed 251.
- Geological and Agricultural Surveys recommended 321—of North Carolina, contemplated by Prof. Olmstead 324.
- Glanders in horses, description of, and remedy for 5.
- Glass lamps, remarks on the proper shape of &c. 22.
- Good's System of Medicine, extract from, recommending salt as a remedy for rot in sheep 353, 354.
- Gold Thorns, Esq. his description of a good horse 394.
- Gout, said to be cured by wearing oiled stockings & worsted ones 30.
- Gratting, John E. Howard's remarks on 242—all limbs of a tree should not be taken off at once grafting—see further engrafting.
- Grass seeds, remarks on the sowing of 301—best s in the spring 301—necessary to sow a sufficient quantity of 301.
- Green colour, new formed by a decoction of tobacco sulphate of copper, linseed oil, &c. 54.
- Green corn, profit and economy in the use of 217.
- Graves, how preserved on the vines till winter 67.
- Grass grounds should be manured in the Fall 15—should be dressed with compost instead of dung—should be scarified, but not rolled 129—should be fed too closely in autumn 129.
- Grasses, table of by Mr. Buel 161—observations on Mr. Buel 161, 173—remarks on by Hon. W. Wells 252.
- Green, Dr. recommends cool water as a remedy drunkness 37.
- Griffith, Thomas W., his remarks on the best time cutting timber, in order to have it grow again 1.
- Gypsum less efficacious than formerly as manure—remarks on the cause of this effect 348—useful preserve vines from insects 361. See further Ph of Paris.
- H.**
- Habit, remarkable instance of the effects of 133.
- Hall Frederick, Professor of Middlebury College, author of his pamphlets on Mineralogy, 245.
- Hall William, his remarks on preserving Cider isinglass, 179.
- Hammatt Wm. C. his statement respecting a cat 3.
- Kuta Baga, 265.
- Harrison C., his remarks on budding fruit trees, 2.
- Hay Making, remarks on 390.
- Harrow, new construction by Rev. Ephraim Abbot 276, remarks on by the Editor. 278.
- Heat, how produced by friction of a solid and fluid 114, crops of, how perpetuated. 492.
- Hedge Fences, queries respecting by James White 345—experiments of Josiah Quincy on raising 18—how, while sitting on eggs should be well fed, 18—ins, a disorder called the gapes in, how cured 3.
- Herod Thomas, notice of storing Mangel Wurtzel, 1.
- Hessian Fly will not attack the Lawler wheat, 2.
- Hitchcock, Rev. Edward, notice of his discourse Natural History, delivered before the Berkshire dist Institution 149.
- Hill Leonard, his statement relative to raising In Corn, 285.
- Hoing corn and potatoes, remarks on by Cultivator 361—strictures on said remarks, by a writer in

- Windsor Vermont Journal, and the Editors' reply to those strictures, 398.
- Hogs, marks on good ones, 49—none except breeding sows, should be kept over winter 49—different opinions of Farmers respecting the keeping them always shut up, 49—how fattened on potatoes and grain without water 49—should have a post to rub against 50—will not thrive if kept in a yard, and fed with clover cut with a scythe 50—boiled or steamed clover will keep through the winter, 56—great advantage of boiling, steaming or baking food for, 50—notice of large ones 219—scorching the hair from, said to be better than scalding, 291.
- Hops, on the curing of by Israel Thorndike, Esq. 38—on an essay on cultivating and curing of by Wm. Blanchard, Junr. 52—remarks on the choice of by Mr. Cobbett 118.
- Fluoride, improvements in, by Mr. Dyer 219.
- Horse Rake, a description of by Thomas Gold, Esq. 394
- Horse, remarkable instance of malice in, 16—Longevity of, 227.
- Horses, Mr. Lovett Peters, remarks respecting the cause of slavers in, 58—see further, salivation, symptoms and cure of Glanders, 204—new system of shoeing 366—how saved from baros on fire 383—disease in called the "big head," notice of, 388.
- Horticultural Society of London, notice of their mission to this country 39—of New York, extract from their minutes, 62—remarks on, 293.
- Horse Checker, improved patent, notice of 290.
- Horticultural Tour, extract from a Journal of, through some parts of Flanders, &c. 103.
- Horticulture, remarks on 185.
- Hot-houses and gardens in Hoxton, Eng. notice of 109.
- Housewives, ironical rules for 340
- Howard John E. his remarks on grafting, 242.
- Howard Thaddeus, statements of his mode of cultivating a crop of Indian Corn, by which he obtained one hundred twenty two and a half bushels and seven quarts to an acre 292
- Howe Frederick, Esq. his address to the Essex Agricultural Society, 235, 244—his remarks on killing land 233—on mineral manure 236—supposed that lime for manure would be particularly beneficial in the county of Essex, Mass. his observation on gypsum, sand clay, &c. 234—thinks the want of root crops a great defect in American Husbandry, 235—that Farmer's products should all be of the best kinds 235—comparison of the advantages enjoyed by English and American Farmers, 244.
- Hull William, an account of his raising an extraordinary crop of Indian Corn, 268—his manner of securing it in autumn, 292.

- Lee William, Consul of the United States at Bordeaux, notice of his work on the cultivation of the vine 112.—Leghorn hats, made of the common red top grass, notice of 13.
- Lead, the acetate of, sometimes used in dressing cheese, the public cautioned against 389.
- Lemon, weighing 14 ounces, raised in Burlington, New Jersey 22.
- Leslie's river-glass, for seeing objects beneath the water, notice of 251.
- Lightning, means of preservation from, recommended by Sir Humphrey Davy 54.
- Locust trees, insects infesting 261, 262—seeds of, how prepared for planting 316.
- Lightning rods, notice of errors in the construction of 77—communication respecting 94.
- Lime, said by some philosophers to be exclusively the product of animalization 22—its use in raising wheat 41, 42—queries concerning, with the answer 54—remarks on its effects in Scotland 56—antidote against the worm grub in potatoes 70—stacked in a well frees it from foul air 162—remarks on the mode of preparing and applying to wheat crops 292 on the use of in gardening 225—remarks on by Yeoman 244—further remarks on its use 374.
- Lime stone, discovered in Bedford, N. H.
- Lined jelly, receipt for making 397.
- Linsed oil for fattening cattle, remarks on by John Prince, Esq. 297.
- Linen, improvement in the bleaching of 13.
- Literary men, observations on the disorders of 352.
- Little Joseph, his statement, relative to raising a large crop of turnips 292.
- Little, Messrs. Henry and Tristram, statement of their premium crop of turnips 171—their statement of raising a large crop of Indian corn 276.
- Lice on apple trees, remarks on by Joshua W. Carr, Esq. 345—by E. Perley, Esq. 355—destroyed by a persevering use of white wash made of lime 358—remarks on by Mr. Preston, 377—may probably be destroyed by hot water 377—Goose oil recommended as a remedy against 382.
- Longevity, remarkable instances of 280—comparison of between New England and South Carolina 411.
- Lovell Timothy, his humorous remarks on trifling laws 192.
- Lowell, John Esq. his notice of Thomas Andrew Knight, Esq. and his improvements 92—his observations on introducing new kinds of potatoes and other vegetables 92—copy of a letter directed to from T. A. Knight, Esq. 93—his remarks at the Brighton Cattle Show 94—his remarks relative to a letter and present of new varieties of fruit from T. A. Knight, Esq. 217—his observations respecting a remedy against the canker worm 281.
- Lycenum, in Pittsfield, Mass. notice of 149—Gardiner, Maine, address of the Trustees to 176.
- Lucerne, its culture, recommended 300.
- M.
- McBine for threshing rice, invented by Tyler and Andrews 349.
- Machinery, remarks on the power of in spinning cotton 204—for slungles, by Willard Earle 369.
- Maconbee's process, for a patent relative to reclaiming boggy land 218, 263, 236.
- Maguey, a valuable plant, a native of Mexico, and raised in Florida, notice of 5.
- Malt, remarks on the choice of, by William Cobbett 118.

- Manumoth a, discovered in New Jersey 360.
- Mangel wurtzel, on feeding ewes with 3, 131; remarks on the cultivation and uses of, by Mr. John Hall 53—manner of storing in England 204—of large growth, notice of 227—great crop of 234—mode of raising 294—remarks on by Leonard Phillips, jr. 294, 295—an excellent food for stock and raised at a less expense than carrots 134—will not endure frost 204.
- Manufacturers' meeting and circular letter for the purpose of petitioning for increasing the duties on woollen goods, &c. 114.
- Manure for grass grounds 129—(See further, Grass Grounds)—how best obtained from swine, and comparative value of, &c. 173—various sorts of used in Great Britain 194—barn yard manure, not a proper application to soils in all cases 196—divided into two classes, animal or vegetable and fossil manures 219—should be spread and ploughed in as soon as carted into the field 286—may be applied to land in two great quantities 296—table of, by Mr. Closs. 296—manner of making compost by Isaac Alden, 32, 292—how managed when cattle are yarded nights 334—summer, how to manage 373—how made by swine 374.
- Maple bird's eye recommended as an article for cabinet manufacture 67.
- Maple tree sugar, remarks on making 298, 341.
- Marle, remarks on its uses and qualities 261.
- Marsh meadows, best mode of reclaiming, 395.
- Mead, a receipt for making 325.
- Mechanics, hints to 211—ought to be supported in the towns to which they belong 165.
- Medical School in Boston, communication respecting 13.
- Meats, preserved by dipping in a ley made of wood-ashes, &c. 5.—preservation of 153.—an easy mode of preserving fresh, during winter, and till late in spring, as practised by the religious society, called Shakers, in Canterbury New Hampshire 235—economy in dressing inferior pieces of 321—how preserved in Tunis 307—is best and most wholesome when the animal has arrived to maturity 329.
- Meteorite stone, notice of, which fell in Nobleborough, Maine 43.
- Mice, made profitable for turning machinery 80—wild thyme said to be an antidote against 253.
- Middletown, a writer with that signature, his remarks on the grub worm 192.
- Milk, that which first comes from a cow more strongly impregnated with any peculiar flavor than that which is last drawn 81—the last drawn makes the most and the best butter 81—remarks on its preservation, and the reason why the last drawn is the richest 317.
- Milking cows by the introduction of tubes or straws into their teats, notice of 377—the practice may, in some cases, be dangerous 376, 406.
- Millet, remarks on its cultivation by the Hon. Bushrod Washington 307, 306—by John Hare Powell, Esq. 345, 307—query concerning by Joel Aldrich 345.
- Miner's safety lamp, account of 378.
- Mitchell Dr. Samuel, L. his description of the capture, figure, &c. of an enormous fish 83.
- Money matters, bad management in 390.
- Monroe Captain Charles, notice of his improvement in tanning leather 367.
- Moon, its supposed influence on the seasons, from the Edinburgh Magazine, 12—remarks on its influence in vegetation 361.
- Morrill, Governor of New Hampshire, extract on the subject of agriculture, from his message 366.
- Morris James, states that botts in horses may be prevented by giving them each a handful of salt once or twice a week 291.
- Mouldiness in paper, books, &c. prevented by oil of Lavender 3.
- Mouse tread mill for spinning cotton 96.
- Mustard, every man who has a garden should raise his own 227.
- N.**
- Nettle, remarks on its uses 229—on the stings of 413.
- Nova Scotia, notice of agricultural improvements in 357, 361.
- O.**
- Oats, remarks on the cultivation of 316.
- Observer, his prescription for taking the taste of turnips from butter 259.
- Oil, how purified for the watch makers 21—of tansy, caution against drinking it by mistake 150.
- Oil gas, used in London, notice of 262.
- Olmestead, Professor of the University of North Carolina, proposes to commence a series of geological and mineralogical observations 325.
- Ombrod James, Esq. notice of his present to the Mass. Agricultural Society of a new kind of grass, called Erba Medica 11.
- Onions, how to preserve the eyes from the operation of white peeling 227.
- Opium, a premium given in England for its manufacture from poppies raised in that country 13—notice of cultivated in Pennsylvania 144.
- Opodeldoo, receipt for making 219.
- Oranges and lemons, how preserved in sand 325.
- Orchard, remarks on the cultivation of 42, 67—trees in, distance at which they should be planted 67—season for planting 67—ground should be kept loose about 67—moss on, how remedied 67—remarks on the manner of pruning by Mr. Knight 130—but little regard paid to, by many farmers 245.
- Osgood Mr. notice of his currant vintage 22—his remarks on rose bugs and a kind of lice which injure fruit trees, &c. 402.
- Owings Nimrod, his communication respecting botts in horses 84.
- Oxen, notice of a number, very large 47, 151, 211.
- Oysters, a bed of found in Connecticut river 111—warm milk recommended for when too many are eaten 163—shells of, uses of 219.
- Oyster shells, possess no medicinal powers superior to common lime stone or chalk, but lime made of, bet-calculated for plastering walls in damp situations 219.
- P.**
- P. his remarks on the mangel wurtzel, and feeding ewes on it 3.
- Palmer D. his remedies on the disease caused by the poison of ivy, 48.
- Paring and burning, remarks on 206—to be used where the soil will produce a great quantity of ashes 222—recommended by Sir John Sinclair for subduing fen and peat soils 222—not proper for a sandy soil 222—burning without fire described 223—instruments used for in Great Britain 230—modes of as described by Sir John Sinclair 230—remarks on from the Farmer's Assistant 246—Mr. Cobbett's mode of 246.
- Parkes Samuel, Esq. notice of his chemical Essays, and extracts from the work 354.
- Parsley, said to preserve horses from salivation 79.
- Parsnips, contain a portion of sugar which may be made into wine 163.
- Pastures, remarks on the management of 334—cattle should not be turned into too early in the spring 334—grazing animals should feed on in succession 334.
- Patrick John, his remarks on the cultivation of lucerne 390.
- Peach trees, remarks on 241—secured from worms by placing ashes about their roots 241—further remarks on 261—hot water turned on the trunk a little above the ground, supposed to preserve against the borer in 261—slacked lime useful to preserve against the borer in 261—only the best kinds should be cultivated 261—may be secured from worms by putting a coat of lime mortar round the body 291—worm in, distinct from the apple worm, and not a borer 261—remarks on by a subscriber 323—new varieties, presented by Thomas Andrew Knight, Esq. to the Massachusetts Agricultural Society 93, 94.
- Pear trees, insect in, and how to preserve against the scolytus pyri 28—remarks on an insect in by A Farmer 42—remarks on diseases of 324—manuring too high and trimming too much thought to give them a disorder called the kibes 324.
- Peck Professor, his remarks on certain insects which infest fruit trees 82, 282.
- Perkins Col. letter from to the Massachusetts Agricultural Society with a cask of flax seed presented to said society 267.
- Peas, a method of preserving green for winter 78—remarks on the cultivation of 302.
- Perkins' steam engine, a drawing and description of 60—notice of 62, 131, 363.

NEW ENGLAND FARMER.

PUBLISHED BY THOMAS W. SHEPARD, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

VOL. II.

BOSTON, SATURDAY, AUGUST 2, 1823.

No. 1.

from the Philadelphia Journal of the Medical and Physical Sciences.

We have much pleasure in presenting to our readers the ensuing essay, in which is traced with considerable success, the natural, botanical, economical, and medical history of the potatoe. It is the production of one of our pupils, who was, at our suggestion, to the investigation of the subject, more particularly with a view of testing by further experiments, the validity of some recent reports by Dr. Latham, of London, relative to the medicinal powers of an extract from the leaves of this vegetable. These reports, we regret, have not been confirmed, and can only account for the discrepancy in the result, by supposing, that the potatoe, as so commonly appears with regard to plants, has undergone a change in this country, by which its narcotic principle is lost, or impaired, from the influence of climate, or peculiarity of culture, &c.

An Essay on the *Solanum Tuberosum*. By H. C. WORSHAM, M. D.

The *solanum tuberosum*, according to botanical writers, belongs to the class pentandria, order monogynia, and of the natural family Luridae: Linnæus, and solanæ of Jussieu. It is known by the following characters.

"Root bearing tubers. Stem herbaceous, not woody, segments of the leaves unequal, alternate—pedicles pointed, corolla five—angular." The natural history of this plant, seems not so well settled as its botanical characters. Its discovery and native history are, indeed, involved in doubt and obscurity, and rendered still more intricate to trace, from the little attention they have received. That the history of this important vegetable, which now forms alike the rich man's luxury, and the poor man's bread, could not be in common with other subjects of so much interest, have received the attention of the naturalist, is a circumstance not readily to be explained. It is, however, generally believed to have been indigenous to this country, as far as we can determine, from the few vague and unconnected remarks to be met with in different authors. Yet there are not wanting others, who assert the contrary, and consider it to have originated in South America—among those are Cicer, Gomara, and Acosta, who wrote about the middle of the sixteenth century, and by whom it is told, that the inhabitants of Quito and its vicinity, have beside maize, a tuberous root, which they eat and call papas. Clusius supposed this to be the *convolvulus battata*, which he received from Flanders in 1593, during his residence at Vienna, under the name of taratouff, an appellation by which the Italians distinguish the tuberous roots—and this conjecture appears to be confirmed by travellers, who have since visited that country. If this had been the *solanum tuberosum*, how, as Clusius asks, "could we have knowledge of it have been so long in reaching us?" and continues he, "how could they have been ignorant of it at Padua, until I sent it from Frankfurt?"

In his characters of the kings of England, old describes the introduction of this plant into England, to Sir John Hawkins, who brought it

from Santa Fe, as early as the year 1565. But little foundation existed for such an assertion, as appears from his own description. It is doubtless, the *convolvulus* to which he alludes, as we have no account of the Virginia potatoe so early as that period. I state this upon the authority of Miller, as I have not been able to lay my hands upon the description alluded to—which may, however, be seen by reference to the Gentleman's Magazine, for the year 1739. From the most authentic accounts, it would appear, that the potatoe now so extensively cultivated on the continent of Europe, was carried thither by Sir Walter Raleigh on his return from Virginia, in the year 1586. There is some doubt, however, whether Sir Walter ever carried it, or that it was afterwards sent to him by Thomas Greenville, or McLane, the first governor of Virginia. Mr. Thomas Herriot, one of the colonists who went out with them, wrote an account of the root called openawk, which he describes in the following manner. "The roots are round, some as large as a walnut, others much larger: they grow in a damp soil, many hanging together as if fixed on ropes, they are good food either boiled or roasted."

It is plainly to be seen from this description, that the root under consideration, is the one to which he alludes, and that openawk is nothing more than the Indian name for the potatoe. The authority, however, for the fact does not rest with those writers. We are told by Gerarde, that he received roots from Virginia, in 1597, called norenbéga, which prospered as well in his garden, as in their own native country. He called them Virginia potatoes, to distinguish them from the *convolvulus battata*, which was at that time much better known and called potatoes, from the Spanish name *battata*. He thus describes them. "The root is thick, fat, and tuberous, not much differing in shape, colour, or taste, from the common potatoe, saving that the roots are not so great nor long, some of them round as a ball, some egg fashion, some longer, others shorter. It groweth naturally in America, where it was discovered." Bauken also observes, that the potatoes came from Virginia into England, thence into France, and other countries.

Writers are not sufficiently agreed, as to the time when the potatoe was introduced into Europe. It was certainly cultivated and used for food by the Irish, long before its utility was known in England. It is stated by Mr. Campbell to have been introduced into Ireland about the year 1610, and by Miller as late as the year 1623. Why they should have assigned so late a period to its introduction, is not easily accounted for, when we are informed by Gerarde, that he cultivated it in 1597. It is no easy matter to reconcile the statements of those different authors, much less to divest the subject of that obscurity, with which it seems to be enveloped. The most generally received opinion, and that which is substantiated by far the greater mass of evidence, ascribes its introduction to Sir Walter Raleigh on his return from Virginia, in 1586. Gouge in his edition of Camden's Britannia, states, that Raleigh planted the potatoe at his re-

sidence, Youghall, in the county of Cork. An anecdote is also related of his gardener, which sheds such additional light upon the introduction of the potatoe into Ireland, that I hope I shall be excused the liberty of transcribing it. On his return he gave some of the potatoes to his gardener, as a fine fruit from America, and ordered them to be planted in his kitchen garden. In August the plants flowered, and in September produced the fruit. But the berries were so different from what the gardener expected, that in an ill humor he carried the potatoe apples to his master, and is this (said he,) the fine fruit from America you praised so highly? Sir Walter either was, or pretended to be ignorant of the matter, and desired the gardener, since that was the case, to dig up the weed and throw it away. The gardener, however, soon returned with a fine parcel of potatoes. I have thus been particular in introducing this anecdote, because it clearly shows that the potatoe could not have been generally known at that time. It will also be perceived by Sir Walter's instructions, the high importance in which he held it, as well as the attention he wished it to receive, by specifying the spot where it was to be planted.

The potatoe from Ireland, gradually made its way into England, as some say, by the accidental shipwreck of a vessel on the coast of North Melos, in the county of Lancashire, a place even now famous for the production of this vegetable in the greatest perfection. Its cultivation was for some considerable time confined to this section of country. Nearly half a century elapsed before it received any attention in the vicinity of London—and it was considered even then, as a mere article of luxury, without any conception of the vast utility that would arise from bringing it into general use. Such, indeed, was the little attention it received, that it lingered in obscurity until the year 1662, when the Royal Society considered it as an article of national importance, and recommended its general cultivation. The potatoe did not make its way into France as early as might have been expected, from the high recommendations it received in England. Lister, in his journey to Paris, in 1693, informs us, that the potatoe at that time was scarcely to be found in the French markets. Its fortune there, appears to have been various, and determined very much by the sudden revolutions which have particularly characterized that nation. Miller tells us, that it was not much cultivated till the year 1742—and in 1749, it fell into contempt—and its cultivation left wholly to the lower class of people. Its importance, however, soon began to revive, and claim a general notice, when, by a sudden fluctuation of opinion, it again lost its reputation. Yet it was not doomed to slumber long, for the necessities of the people had driven them to invention, and they were willing to seize upon any thing that would be likely to resist the ingress of famine. The prejudices against its introduction still, however, continued, amidst this vacillation of opinion, until the production of bread made from the farina of the potatoe in combination with wheateo flour. This at least, gained its

it a temporary reputation, and seemed to insure it a durable existence, though there was still something wanting to fix its character as a wholesome article of food—which was reserved for Parmentier, who, in 1773, brought forth a specimen of bread from the farina of the potatoe alone. In Germany its fortune was not so precarious. It appears readily to have paved its way, and to have been cultivated as early as the year 1601—since, Clusius says, *ca plerisque Germanie hortis satis vulgaris dudum facta*. In Italy its fate was nearly allied to that experienced in France: so great, indeed, were the prejudices which it had to encounter, that, we are told, a ship load of the roots having been sent from England to Naples, to relieve the inhabitants of that place, who were then the victims of famine and disease, the mere name of potatoe, as food, carried with it such dread, that they chose rather to bear the horrors of their situation, than purchase the article. But happily for that portion of country, those prejudices gave way to the magic wand of science, and the potatoe now supplies the food of those wretched vagrants, who were before doomed to subsist on the watery ground.

In Scotland, Sweden, and Burgundy, it had to contend alike with the obstacles which had so long opposed it. But it is gratifying to learn, that the potatoe is ultimately finding its way into the remotest corners of the earth, and is now, nearly every where, cultivated for the benefit of mankind.

Esculent Properties.

The reputation of the potatoe, as an esculent, wholesome vegetable, is too well established, as has been already intimated, to require any further attention from me. Its use for food appears to have been co-existent with its discovery: we can find at least, in its early history, no trace of its application to any other purpose. Especial objections, however, were formed against it on account of its place among the solana. In Burgundy, we are told, its culture was interdicted in consequence of its supposed mischievous properties. Among the fancied effects produced by it, were leprosy and dysentery. Those prejudices, no doubt, originated from its exposure to the sun and weather, by which its natural qualities were destroyed, as the means of preserving it were, at that time, very little understood. Many accounts of injurious effects are to be met with. But such representations do not prove the unwholesomeness of the root, since it has constituted the chief article of food to vast numbers of people for upwards of a century. The dependence of England and Ireland upon it for food, is such, indeed, that it is emphatically styled the "bread root" of those countries. Nor is it much less extensively raised in the highlands of Scotland, where scarcity or famine was too frequent an occurrence before its introduction. It is said that many of the inhabitants of Banff, a small district in that country, in the year 1733, must have fallen victims to famine, had not the potatoe been supplied. In Wales, its cultivation has become general, as we are told, that potatoes and barley bread form the chief sustenance of the poor—and what at this time occasions the calamitous situation of Ireland, save the failure of this important crop? Two millions of people are by this circumstance deprived of the very sustenance of life, and destined to drag out an existence, at best intolerable.

Even in the early history of this vegetable, we find the attachment of the Irish to it strongly marked, and the fancy of the poet inspired to celebrate its praises.

"Leek to the Welsh—to Dutchmen butter's dear,
Of Irish swains potatoe is the cheer."

The success which now attends the rearing of this vegetable could not have been anticipated, even by the most sanguine, from the many formidable obstacles over which it had to triumph.

Having its origin in a warm climate, it was supposed to be intolerant of cold, and upon that account, incapable of cultivation in more northern climes. But experience has shown the contrary, and the potatoe is naturalized almost in every region. With the lower classes of people, it is one of the greatest blessings that the soil produces, forming "flour without a mill, and bread without an oven," and at all seasons of the year, an agreeable, wholesome dish, unaided by expensive or injurious condiments. What resources does the potatoe present to us? Its stalk, considered as a textile plant, furnishes in Austria a sort of flax—when burned it yields much potash—its apples when ripe and crushed, ferment and give spirits by distillation—its tubercles made into a pulp, are a substitute for soap, in bleaching. Cooked by steam, the potatoe is most healthy food. By different manipulations it furnishes two kinds of flour—a gruel and a parenchyma, which may be applied to increase the bulk of bread made from grain. Treated chemically, it is converted into beer, vinegar, spirits, &c.

It will be perceived, that the potatoe is susceptible of a very wide and diversified application, and highly deserving the attention of the agriculturist. Numerous experiments have already been commenced, and considerably extended on the farina of this vegetable, and by which it appears to be equal in nutritious properties to that of any other article. From some comparative experiments by Mr. Whately, of Cork, it is plainly shown, that the same quantity of land cultivated in potatoes, will produce one half more farina, than the same land applied to the production of farina from wheat. He also appropriated the farina of this root to the making of bread, biscuit, and pastry, with different proportions of flour, and found that they resisted better the effect of climate, than when made wholly of wheaten flour. It seems, indeed, to have a remarkable power of preservation, as Mr. Whately states, he has known the flour to keep good seventeen years. The farina possessing all the nutritious parts of the potatoe, and being perfectly bland and digestible in its nature, may be supposed to form an excellent article of diet for the sick. In the shops of Europe, a composition vended under the title of solomina, and recommended as a nutritious diet for children and sick persons, is said to be essentially, the farina of potatoes.

It is obvious, from what has been stated above, that the potatoe does not hold its reputation exclusively, as an article of diet. The potash in such quantities has been obtained from the combustion of its leaves, that it is supposed from the facility with which the process is effected, that France will be released in a great degree from the heavy sum she pays this country, in the purchase of that article. It also appears by the

experiments of Dr. Anderson, that ardent spirits in considerable quantity may be obtained from the distillation of the potatoe. From seventy pounds of the bruised roots, he obtained one gallon of pure spirits, considerably above proof, and about a quart below proof. The potatoe has also been made the subject of analysis, by several distinguished chemists, among whom is Vauquelin, who, from a careful investigation, drew as a conclusion, that the potatoe was composed of starch, of parenchyma, of a peculiar animal matter, and of certain salts. The existence of these principles does not explain the cause of the spirituous fermentation which they undergo when exposed in the ordinary manner to a requisite temperature. It became then a desideratum to discover the substance which, in the potatoe, supplies the place of saccharine matter to which alone this peculiar process is conceived to be owing. By a well regulated set of experiments, made by Dr. Reshier, it is shown to contain sugar and gum, in the proportion of sixty-four grains of mucous sugar, to two hundred and twenty grains of gum in the pound. It also appears from the experiments of Vauquelin, that resin and animalized matter are the only sapid ingredients of the potatoe, and give it the superior flavour, perceived when the article is eaten roasted, and which is necessarily lost by boiling.

[The remainder of this article consists of statements of experiments for ascertaining the "medical properties" of the potatoe plant, which can be interesting only to physicians. It concludes as follows:

"The extract of potatoe on the whole, must, I conceive, be now regarded, if not wholly inert, at least far inferior to cicuta, or any other article of the same class, retained in the Materia Medica. Why then should we endeavour to store our Materia Medica with useless lumber, and add uncertainty to a set of remedies, that already begin to decline in the confidence of physicians?"

We are not able to say whether the kind of wheat described in the following article preserves its reputation for being impregnable to the attacks of the Fly. The subject, however, is worthy of further inquiry, and we would thank our friends and correspondents for any information they may be in possession of relating to it.

From the National Intelligencer.

Buckland, Va. May 10, 1817.

The ravages of the Hessian Fly, of which we have so general accounts this season, are certainly a subject of melancholy concern. As far as I have been able to learn, in all the counties of Virginia where the growth of wheat is sufficiently advanced to produce the discovery of the visitation of this insect, it has invariably appeared. And I now very much lament that some of my neighbors, or myself, did not, last year, give publicity to the facts on the subject, which for several years have been known to us, and of which the present year affords additional evidence.

About five years ago, a kind of wheat was introduced into this neighborhood, which has been found, by invariable experience, to resist the fly. It was brought here by James Lawler, in a small quantity in his saddle bags, from Chester county, Pennsylvania, where he had been on a visit to his friends. He stated, that it was there called Jones's White Wheat, and had never been in-

fectured with the fly. From this circumstance considerable attention was paid to the propagation of it. The second year after it had been cultivated in this neighborhood, I was so fortunate as to get five bushels of it; I sowed it on one side of the field of about 120 acres, the balance of the field in the golden beard; there was no difference in the soil, and the Lawler wheat produced eleven for one, while the other did not exceed three for one. The fly that year was very fatal, and the golden beard, which was sowed much more thick than the other, became, after the commencement of spring, thin and scattering, and continued to decline in prospect; much of that which had survived falling till it was harvested, while the Lawler wheat grew to a fine height, and was without any fly in it.

I sowed the succeeding year my product of fifty-five bushels, and twenty more, which I obtained by giving four bushels for one. I sowed that year 270 bushels of different kinds, and made as much from the seventy-five of Lawler wheat as from all the rest, for that was also a fatal year to the general crops, from the ravages of the fly. I afterwards sowed my whole crop of the Lawler wheat; but the last fall, being lulled into a false security, from the circumstance of the fly not having made its appearance the preceding season, I sowed a portion again of the earled wheat, in order to divide, for convenience, the time of the harvest coming in, as the Lawler wheat comes later than any, except the old yellow bearded wheat generally in use some ears ago, and is about as late as that. But this year has again more fatally testified to the value of the Lawler wheat. I have almost wholly lost my seedling of the golden beard, while the other has continued to grow in proportion to its benignity of the season, and has a perfectly faithful appearance, without the trace of any fly; while in that adjoining it, of a different kind, you may immediately see deposited in the stalks, six, eight, or ten of the embryo. Among my neighbors, as far as I have learned of the state of their crops, the same result has occurred. The Lawler wheat is invariably exempt from fly, and every other kind is invariably destroyed.

Experiments were, in the first three or four successive years after its introduction, made of its efficacy, with the most satisfactory success, will only mention one:—Mr. John Brown, in the fall of 1814, sowed equal quantities of the purple straw and Lawler mixed; the fly commenced its depredations as usual in the spring, and by harvest scarcely a straw of the purple wheat was left, while the Lawler remained one, and apparently uninjured.

Of this valuable wheat much was this year found, the anxiety to get of the seed having misled, from the favorableness of the last season. At some other time it may be proper to sign the reason of this extraordinary exemption, if indeed they can be satisfactorily traced, of which there is much doubt, if not, we must content ourselves with the utility of knowing a fact.

To those who cultivate it, my experience would lead to the recommendation of sowing it thicker than usual, although it branches more early is common, and of plastering it in broad cast early in the spring, in preference to any other mode, both as means of sustaining its maturity, and enhancing its increase, it being a late wheat of tall growth.

A SUBSCRIBER.

ON FEEDING EWES WITH MANGEL WURTZEL.

From No. 745 of the Farmers' Journal.

Some persons having stated that Mangel Wurtzel will grow where they cannot get a crop of Turnips, the following extract is made for their satisfaction, from the Farmers' Journal.

It is however considered by some practical men, as dangerous to give breeding ewes too much of this root at first, causing them to shed their wool. Increasing the quantity is thought the best practice.

Herefordshire, December 12, 1821.

SIR—As I consider it to be the duty of every individual connected with the Agricultural interest to communicate to the public the result of satisfactory and beneficial experiments, I will briefly answer the several queries of M. W. in your Journal of this week.

From the principal part of my turnip crop failing in the year 1820, I was compelled to feed my stock on my crop of mangel wurtzel: the ewes, before lambing, were taken off the few turnips I had, and put into the fold, where they were fed with mangel wurtzel, and a very small quantity of hay, and without water. After lambing, they were given the same food, and from the great flow of milk produced, the lambs were in very high condition. The whole of my flock were kept entirely on this food, from the beginning of January, 1821, to the end of March, during which period I weighed eight wether sheep, and put them into a barn, when they were given twenty-five pounds of mangel wurtzel, and about five pounds of good hay for each sheep every twenty-four hours, for five successive weeks: some of them gained more than others; but on weighing them out, at the expiration of that time, they had increased, upon an average, eight pounds per quarter. I can also state that, having killed several of the sheep, the mutton was particularly mild and sweet. I am fully persuaded that there never was better food for sheep, or food that will create so great a flow of milk from the ewes. If you consider this a sufficiently minute reply to the queries of your correspondent, I think the sooner it is made known, through the medium of your valuable Journal, the more satisfactory it will be to M. W.

I remain, your well wisher, P.

P. S. It is necessary to observe, that the mangel wurtzel must be carefully cleaned, without washing, and given whole.

Dandy Looms.—A hand-loom on a new construction, and which has received the appellation of "Dandy Loom," has recently been introduced at Blackburn. Its principal advantage over the common hand-loom consists in its being much smaller, and in the application of a crank, by which, as in steam-looms, the number of picks of weft in an inch is regulated, and the cloth consequently made more even. We understand also, that the new hand-loom weaves the yarn without dressing, which is an expensive process; whilst by the use of a copper-shuttle, the necessity of winding the weft is superseded. The loom measures only about 30 inches in depth, from the cloth to the yarn beam, and its cost in wood is not more than 35s. or 36s. or in iron than 52s. 6d. A fair weaver, with tolerable exertion, will weave a piece of 25 yards in eight or nine hours. By many manufacturers, we understand the improvement is considered of some importance. Indeed, it is

conceived that it will ultimately supersede the hand-loom on the old construction; and, perhaps on some particular goods, successfully contest the further progress of power-looms.

From the Providence Journal.

Progress of Commerce and Manufactures in the West.—A day or two since, a gentleman from Pittsburgh, Penn. passed through this town, on his return to the West from a commercial expedition to Boston. He brought with him from Pittsburgh, an extensive invoice of Window Glass and Glassware, which he disposed of in handsome advance, on original cost, charges and incidental expenses. The rise and progress of Pittsburgh is, perhaps, unexampled in the annals of towns or cities, and the enviable height to which it has already attained, is highly complimentary to the enterprise and industry of the hardy sons of Pennsylvania. Forty years since, the scene on which the town stands, was a howling wilderness, and with the exception of the marks of civilization discoverable in the construction of Fort du Quesne, it presented nothing but a cheerless wild, the abode of the savage, and the resort of the yelling beasts of the forest. It now contains from 7 to 10,000 inhabitants and nearly two thousand houses, many of which are splendid and elegant. As a manufacturing town it is exceeded by but few in the United States, and from the extent of their works, it long since acquired, and still maintains, the title of the Manchester of the West. The country adjacent abounds with minerals, such as iron, lead and copper; the former of which has been found in large, and the latter in small quantities. Some years since, ship building was carried on to a considerable extent, but failed when our commercial embarrassments commenced, and is now entirely abandoned.—In the year 1805 a schooner was fitted out from the place, and sailed for Leghorn. On her arrival at that port the master delivered his papers at the custom house: the collector looked at them with astonishment, and protested there was no such port in the world—you are an impostor, said he, and I must confiscate your vessel. The trembling captain produced a map of America, on which he turned his eye up the Mississippi two thousand miles, then up the Ohio nine hundred, and at the junction of the Alleghany and Monongahela river, almost three thousand miles from the ocean, showed to the dissatisfied collector the port where he sailed from—the flourishing town of Pittsburgh.

To prevent Moulding in Books, Ink, Paste and Leather.—Collectors of books will not be sorry to learn that a few drops of Oil of Lavender will insure their libraries from this pest. A single drop of the same oil, will prevent a pint of ink from mouldiness for any length of time. Paste may be kept from mould entirely by the same addition; and leather is also effectually secured from injury by the same agency.

Prevention of Contagion.—Gauze veils, on the principle of Davy's safety lamp, have been recommended by Mr. Bartlett, as preservatives from contagion. This is a point of so much importance to humanity, that we hope the efficacy of the recommendation will be tried by the most critical experiments.—U. S. Gazette.

From Moubray's Practical Treatise on Domestic Poultry.

THE TURKEY.—*Breeding and Management.*

The turkey-cock is sufficient for six hens, and even more, under the management of some districts, where one breeder keeps a cock for his own, and for the use of his neighbors, who send their hens, and in that mode avoid the charge of keeping a cock: but this practice is exposed to uncertainty, and is scarcely worth following, although whilst the hen is setting, the absence of a cock is no loss, as he will sometimes find the opportunity of tearing the hen from her nest, and in the struggle, of destroying the eggs.

The hen will cover, according to her size, from nine to fifteen eggs, and unless attended to, will perhaps steal a nest abroad, in some improper and insecure place. The turkey hen lays a considerable number of eggs in the spring, to the amount of eighteen to twenty-five and upwards, and her term of incubation is thirty days. She is a most steady sitter, and will sometimes continue upon her eggs until almost starved, rather than quit her nest: hence the necessity of constant attendance with both victuals and water. She is also a most affectionate mother; and that most curious and accurate observer, Buffon, remarks her soft and plaintive cry, with her different tones and inflections of voice, expressive of her feelings. These facts, however, are to be received with a due degree of circumspection, since I have known unsteady sitters among turkeys, and however affectionate, the turkey hen, from her natural heedlessness and stupidity, is the most careless of mothers, and being a great traveller herself, will drag her brood over field, heath, or bog, never casting a regard behind her to call in her straggling chicks, nor stopping while she has one left to follow her. She differs beside, in this particular, from the industrious common hen; she never scratches for her chicks, leaving them entirely to their own instinct and their own industry. On these accounts, where turkeys are bred to any extent, and are permitted to range, it is necessary to allow them a *keeper*. The turkey hen is nevertheless extremely vigilant and quick in the discovery of any birds of prey in the air which may endanger her brood, and has the faculty, by a peculiar cry, of communicating her alarm, on which the chicks immediately seek shelter, or squat themselves upon the earth: but she will not, from her timid nature, fight for her brood as the common hen will. The domesticated, as well as the wild turkeys, run with considerable speed.

The chicks must be withdrawn from the nest as soon as hatched, and kept very warm. It is a very old and very general custom, to plunge them instantly into cold water, and then give them each a whole pepper-corn, with a small teaspoonful of milk. This baptism is used by way of a prophylactic against catching cold, to which young chicks are so peculiarly liable; but it is a practice which I have never used, and from which, in severe weather, I should suspect danger; however, their being instantly thereafter wrapped in wool or flannel may secure them. The turkey, from sitting so close and steadily, hatches more regular and quickly than the common hen.

The hen and brood must be housed during a month or six weeks, dependent upon the state of the weather. First roo, curd and barley,

meal kneaded with milk, and frequently renewed with clear water, rather than milk, which often scours them. In case of the chicks appearing sickly and the feathers ruffled, indicating a chill from severity or change of weather, we generally allowed half-ground malt with the barley-meal, and by way of a medicine, powdered carraway or coriander seeds. Also artificial worms, or boiled meat pulled into strings, in running after which the chicks have a salutary exercise. It is to be noted, that the above diet is beneficial for every other species of chicks, equally with the turkey. Superfluous moisture, whether external or internal, is death to chickens, therefore all slop victuals should be rigorously avoided. The utmost cleanliness is necessary, and a dry gravelled layer is most proper. A fresh turf of short sweet grass daily cleared from snails and slugs, which will scour young chicks, is very pleasing and comfortable to them, and promotes their health. The above substantial food was always our chief dependence with this brood, nor did we ever find it necessary to waste time in collecting ants' eggs or nettle seed, or give clover, rue, or wormwood, according to the directions of the elder housewives. Eggs boiled hard are equally proper with curd, and generally nearer at hand; the eggs being rotten, is said to be no objection, although we never used such.

Our first preference for water instead of milk for turkey chicks, so much recommended by the old writers, arose from the observation that chickens at large, among the troughs of milk-fed pigs, generally were sickly and scouring, and rough in their feathers; and more particularly so, when they had access to potatoe wash, which not only purged them, but glued their feathers together, keeping them in a comfortless and unhealthy state.

The weather being remarkably favourable, we have usually kept the hen abroad, about two hours in the forenoon, in a moderately warm sun, whilst the chicks were only three or four weeks old, great care being taken that they did not stray far from the coop. Six weeks is their longest period of confinement within doors, after which it is more safe to keep the hen for another fortnight, that the chicks may acquire strength abroad sufficient to enable them to follow the dam, they being naturally inclined to stray too far, and to weaken themselves by fatigue. When full half-grown and well feathered, they become sufficiently hardy, and in a good range will provide themselves throughout the day, requiring only to be fed at their out-letting in the morning, and on their return at even; the same in spacious farm-yards; if confined to the poultry-yard, the food and treatment is similar to that of the common cock and hen. Turkeys would prefer roosting abroad upon high trees, in the summer season, could that be permitted with a view to their safe keeping.

To FATTEN.—Sudden barley, or barley and wheat meal mixed, is the proper food for turkeys confined to feeding; generally their food and treatment are the same with other fowls. They may be fattened early, or may be castrated, a practice not very common, but the bulk of the turkeys are fed for Christmas, or the months immediately preceding and subsequent, when the quantities fat, sent from Norfolk alone, are immensely great; as also are previously the droves of store turkeys. Turkeys share with

the geese in gleaning the corn fields, or shacking, and the former forage over the woods and commons, in the autumnal season, after which they are put up to be completely fattened.

I have heard of the Norfolk turkeys fattened to weigh twenty, and even thirty pounds each, and Buffon relates that the wild turkey of America, has been known to attain the weight of sixty pounds; but I have never made any heavier than fifteen pounds, ready for the spit.

Turkeys are the most tender and difficult to rear of any of our domestic fowls; but with due care and attention, which, rightly considered in all things, give the least trouble, they may be produced and multiplied with little or no loss, and the same may be averred with all truth, of the rest of our domestic fowls, and animals in general: the losses and vexations annually deplored, arising almost entirely from ignorance and carelessness united hand in hand. Turkeys as well as geese, under a judicious system, may be rendered an object of a certain degree of consequence to the farmer.

From the Massachusetts Agricultural Repository.

WET UNPRODUCTIVE MEADOW RECLAIMED. By S. W. POMEROY, Esq. Vice President of the Massachusetts Agricultural Society.

In compliance with the request of the Board of Trustees, I will endeavor to detail the management, in reclaiming a tract of twenty acre of Woodcock-meadow, or swail, upon my farm the contrast between its present and former appearance having attracted some attention. The soil is a light, black, vegetable mould, mixed with fine white sand, upon thin, alternate strata of blue, yellow-veined clay, and the same kind of fine sand. This sub-soil retained all the surface water, and so level and wet was the whole tract, that the hay seldom paid the labor of harvesting; and except in dry summers its value for pasture was trifling;—besides, one quarter was occupied by flag ponds and mounds, the produced nothing. No part, except four acre of the upper end had been subdued, in any other way, than by cutting the bushes and floating the vestiges of a dam for that purpose now remain—a ditch through the centre five feet wide carried off, slowly, the water from the spring of winter floods of the neighboring high grounds. I began at first with ten acres, and the next year the whole was under the plough—it was struck out into lands of from one to two rods wide, as was found convenient, on account of roots, mounds, &c. and in a direction to the ditch; the lands were back-furrowed, as it is called, and the water furrows were cleared out by one or two extra bouts—as the tract was narrow, the ditch being incumbered with roots and its sides unequal, it was found necessary to plough directly across, by which it was nearly filled up. The first heavy rain its content were of the consistence of mortar, and a stop was put to all operations. To have cleared it out with shovels would have been a heavy and expensive job; a plough was tried with very little advantage. A maple sapling, that had been taken up with all its close and horizontal roots, extending four feet, was cut six feet long hitched to a strong team, and with a man mounted on it, was drawn several times through the middle of the ditch, completely scooping out the passage for the water, throwing the mud or

ch side, and filling up the inequalities; the manual labor necessary, was to clear out the mouths of the water-furrows with a shovel, which was soon performed—in the subsequent operations, the maple was frequently resorted to, with similar success. When sufficiently dry the lands were harrowed, in the same direction they were ploughed, and then ridged with a large Dutch plough and two yoke of oxen; these ridges were made by turning one furrow nearly on another, the space being perhaps ten inches, into which the manure was put, and were put five feet apart. In the centre of the ridges potatoes were planted in hills, from three to four feet apart—in cultivating, they were ploughed between the ridges *only*, with a yoke of oxen, or two mules *tandem*, and the earth to be in the hills, taken out of the furrows, so that the ridges remained entire, and the crop secure from too much wet, which otherwise would be destroyed it. As it is not the intention of this communication to state the particulars of a crop, I shall only observe, that it was an average one, with the upland in the neighbourhood—had the manure been more suitable for potatoes it probably would have exceeded; but applying the manure, which was a compost of bones and hoofs from the soap and glue boiler, fermented with leached ashes and sandy soil, I was governed partly by necessity, and partly in view, the preparation of the two first seasons for the permanent crop of grass that to follow, they being of too fiery a nature to be laid down *fresh* with grass-seeds. The next season, the lands as first laid out, were in back-furrowed, ridged, and the same process pursued as before, with less labour, the same kind of manure, and the crop rather better, as soon as it was off, the lands were ploughed in the same manner as before, for the purpose of laying it down; but they were not sufficient to take off the water entirely, and were unequal. Repeated ploughing and harrowing might have produced the desired effect, but it would have been wasting, and it became necessary to try the operation called turnpiking. A scraper, made of thin pine plank four feet long and two feet wide, shod with iron, with a couple of old plough handles fixed by staples recently for a man to hold, and small chains connected with them from the centre, to which chain from a yoke of oxen were hitched. The scraper was then placed in the water-furrow of the first land in such a position as would take up as much earth as the oxen could draw and work briskly. When he came to the centre of the land, which may now be called a *ridge*, the men raised the scraper and folded on to the next, treating each ridge in the same manner till he had gone over fifteen or twenty, he then came about and returned by the side of his former track, till he had performed the same operation over the whole—in some cases a second scraping was necessary. As the scraper was light the men held it up till he came to the water-furrows, or such places as he wanted to take the earth from, and the work was not more than to hold a plough in new rough ground. As there is no stopping, the oxen may work as much in a day as they can harrow or harrow of the same width of the scraper. The ridges had been harrowed level, and the water-furrows cleared out, the whole resembled a field of turnpike roads. To each acre

were spread 200 bushels of dry leached ashes, and 3 pecks of timothy seed, sown, harrowed, and rolled—the sowing was from the 20th September to the 1st November, and on most parts the seed vegetated before winter. It was my intention to have kept a particular account of this enterprise, but the work, owing to wet weather, and other causes, became so blended with other operations of the farm, that it was found impracticable. I believe, however, that the potato crops nearly paid the expense, the two first years; and I am convinced that the whole expense besides the value of the crops, including the extra expense, compared with laying down common upland, did not exceed ten dollars per acre. The crop of grass the following season, owing to the plants being so very young, was light—heads were formed but no seed produced. The hay resembled rowen, and was of more value than any crop the land would have borne had it been sown with the grass seed in the spring, as is usual. The land for four successive years since, without a dressing of any manure, has averaged two tons per acre—not estimated tons, as taken out of the field, but weighed out in the winter and spring in the Boston market, being put in a barn by itself, and an exact account kept of the sales. The last season the crop was lighter, but no water remaining even in the water-furrows, it has become a fine perennial meadow, and with slight top dressing once in two or three years will forever be productive of the sweetest herbage. The value of the land, in the estimation of many who were acquainted with its former state, is thought to be more than quadruple.

It may be proper to state that I have not suffered the land to be fed with any kind of stock, but have some seasons taken a second crop.

Extracts from a letter on the geology and productions of Florida, published in the Charleston Courier.

VALUABLE PLANT.

The *magny* of Mexico, the plant from which is drawn the liquor called the *pulque*, of universal use and celebration in that country, is not a native of Florida, but thrives as well as if it was. It forms a plant, when full grown, from five to eight feet high in the body, and from ten to eighteen inches in diameter, the leaves of it, if I may be allowed the term, for they appear more like huge limbs than leaves, but they must be called leaves, as they are the only lungs of the plant, descend from the top to the ground, and are so thick and heavy that two or three would make a man's load.

At the age of from six to eight years it flowers, by shooting up a stamina from ten to sixteen feet above the plant, gorgeously hung with flowers like a Maypole. Just before it sends forth this exuberance, the change in the colour of the plant indicates its near approach, when a bowl-shaped cavity is cut in the head of the plant, and a cane introduced in the side of it to draw off the liquor. Each plant contains from 50 to 150 galls. of liquor, and dies immediately after; but is succeeded by suckers left in their culture to keep up a constant succession.

This juice carried through a vinous fermentation becomes a liquor resembling cider, but more spiritous, which is sought with avidity by all ranks of society: on boiling and clarifying, it becomes a wine; and on distillation, affords a

fine brandy. The outward coat of leaves yields a membranous substance used for the manufacture of cordage; an inner coat gives a finer substance for clothing, and the internal part of the leaf is an article of food; so that this productive plant regarded by the Mexicans as one of the most beautiful gifts of nature, affords them cider, wine, brandy, cordage, clothing, food and fuel.

From 12 to 15,000 mules are daily employed in supplying the city of Mexico, from the surrounding plantations, with pulque, which is the liquor in a ciderous state. Great estates are held in that country in this article of culture. It is in the flowering of this plant, in a degenerate state, in colder climates, that we are deceived by supposing it to be the aloe that flowers once in a century: this flowers in 8 or 10 years in such climates, and perhaps is not of the aloe tribe; certainly it partakes not of the nauseous bitter, nor cathartic qualities of the aloes we are acquainted with.

AMERICAN CALICOES.

From a Correspondent of the Providence Journal.

An establishment for printing Calicoes will shortly be put in operation at Taunton, Massachusetts, which, when completed, will be a valuable acquisition to cotton manufacturers in that quarter. At Chelmsford a large establishment of this description was put in operation this week. Cotton manufacturing is one of the principal branches of domestic industry, in this State, and at this time requires every attention from those interested in it. The quantity of cotton goods now unsold, is very large, and will probably increase before the fall sales commence; consequently at that time, the sales will be very limited. Calicoes can be made in this country, of a quality superior to most of those made in and imported from Europe, and can be sold equally cheap. I should regret very much to learn, that this State, which has always been considered a manufacturing State, should be the last to commence a new branch of manufacturing, that would give a certain market for a vast amount of cotton goods; I would therefore propose to the cotton manufacturers to form a company for printing calicoes and bleaching, which is a part of the process. The good effects will be immediately perceived from the increasing consumption of American goods.

From the Genius of Liberty.

Mr. Patton—Please give the following a place in your next paper, as it is now time to use it. I have for more than twenty years past, kept meat hanging up in my smokehouse, through the summer season, and no fly worm or bug has injured it.

To prevent such injury, about this time of year, I take clear strong ley made of wood ashes. I commonly boil it to make it stronger than it generally runs off, then I take my bacon and smoked beef, having two or three gallons of the ley in a large iron kettle, I take each piece of meat and dip it into the ley, so that it is completely wetted with it, then I let it dry—then I hang the meat in its former place. By this process I have invariably found that it kept the meat free from bugs and worms, and no taste of ley is ever perceived, not even on the outside.

Yours, &c. JOHN POTTER.

Progress of Science.—A French journal recapitulates, as follows, the advantages derived to science by the late British voyages of discovery in the Arctic Seas:—1. That the continent of America is not so extensive as has been commonly supposed, towards the North Pole. 2. That its northern coasts, though at present inaccessible, lie under parallels less elevated than those of the Asiatic coasts in general, and exceed only by a few degrees the latitudes in the north of Europe. 3. That Baffin's Bay, as it is called, is not properly a bay, but forms a part of the Arctic ocean, communicating with it by Lancaster strait. 4. That Greenland is not conjoined with the Arctic countries of North America, but forms an immense island, or rather a sixth continent (Australasia being the fifth) from the extremity of the great head land which it projects, between Europe and America, to New Siberia, which appears to be its farthest limits. 5. That admitting this, it must be frozen land, and not the Hyperborean Ocean, which fills the 90th degree of latitude and the North Pole. 6. That combining the result of the Polar expeditions with Russian discoveries, there is reason to conclude, that this Arctic continent has been originally subject to the same geological laws as the other great divisions of the globe: its configuration, it would appear, is similar; its greatest breadth being in the northern part, as in the five other continents. One advantage to navigation has already resulted from certain passages discovered by Captain Parry: the whale fisheries have ventured as far as Lancaster Straights, having returned with rich cargoes.

United States Gazette.

New Mode of Preservation from Drowning.—A writer in a Liverpool paper recommends the following very simple method of preserving persons in the water from drowning:—Take a silk handkerchief, and laying it on the ground, place a hat in the centre, with the crown upwards in the ordinary position of wearing, and gather up the corners, giving them a twist to keep them more securely together. Any one may then venture into the water, without being in fear of the drowning person taking hold of him, as the quantity of air in the hat is sufficient to support two persons;—or it might be advisable to place the corners of the handkerchief in the hands of the person drowning, who would thus be kept floating, and easily conveyed to the shore. *Ibid.*

Potatoes.—The following singular statement is given as a fact:—Early Potatoes may be produced in great quantities by re-setting the plants, after taking off the ripe and large ones. A gentleman at Dumfries has replanted them six different times this season, without any additional manure; and instead of falling off in quantity, he gets a larger crop of ripe ones at every raising, than the former ones. His plants have on them three distinct crops; and he supposes they may continue to vegetate and germinate until they are stopped by the frost. By this means he has a new crop every eight days, and has had for six weeks past.—*London paper.*

Canine Sagacity.—The house of a respectable tradesman in Exeter was lately saved from fire, by the sagacity of a little terrier dog. Just as the family were about to retire to bed, the animal

attracted the notice of the mistress of the house, by its repeated and ultimately successful attempts to draw her towards a safe in the kitchen, where she discovered a quantity of candles in a burning state. It appears the servants had indolently and incautiously burnt off a candle from a quantity which were hanging by a string.

From Poulson's American Daily Advertiser.

"KEEP COOL."

When every one is complaining of the heat, this advice will surely be grateful who is confident that he is acquainted with very simple and certain methods, if not of totally preventing, at least greatly mitigating, the unpleasant feelings complained of. An observance of the following rules, has, by the experience of many, proved them to be of this character, and as such are warmly recommended to be pursued:—

Dress must be light both in color and weight; open and loose in texture as well as in the manners of their making.

Never walk during the day without an umbrella, and then do not walk fast, and keep as much as possible in the shade.

Dwellings will be kept perfectly cool if the windows be closed so as to exclude the hot rays of the sun, and not opened until sometime after the sun has set. In those rooms which are in constant use the windows should be bowed, independent of the exclusion of the hot air; moderate darkness is preferable to glaring light.

The brick and stone pavements should be wet at least twice every day; early in the morning and towards sun-set; the evaporation will cool the atmosphere, and temper the heat still retained by them.

In order to sleep pleasantly, the windows of chambers must be kept entirely closed, until after sun-set; then let every aperture be free to the current of the evening air.

Cool yourself perfectly before you go to bed.—Dr. Franklin says he was in the habit of sitting undressed at his window, until he felt pleasant, and did not think a person so doing was liable to take cold.

He also recommends, that when the bed-clothes feel disagreeable, having imbibed the moisture of the body, to shake them, or rather move them up and down, without displacing them, until the air passing through the saturated filaments make them cool and refreshing.

If you are warm sit quiet. Most persons in their violent impatience to lower their temperatures increase them by their efforts.

It is not advisable to check a profuse perspiration by the sudden use of fanning, sitting in what is called a draught of air or removing too much of our dress. Also,

Be cautious in partaking of cold refreshments; the sudden alteration thus produced is in the highest degree dangerous.

Expose yourself no more than is necessary.—Use no more exertion than is absolutely required; early in the morning and in the evening there is time enough for exercise. Avoid excess in every thing.

These are homely but excellent directions. They insure not only comfort but health; they do not merely compose the body to a pleasant state, but settle the mind to its usual and regular operations. If such be their effects, and we know them to be such, they are valuable.

NEW ENGLAND FARMER.

SATURDAY, AUGUST 2, 1823.

'The Farmers' and Gardeners' Remembrance' is unavoidably omitted this week in consequence of some unforeseen avocations, and the necessity of preparing an Index for the first volume. In our next, we hope to take up the thread of our discourse, under that head, and shall continue to spin as long as our staple lasts, and our manufactures find a good market. In the mean time, we shall be diligent in collecting and arranging materials to form the topics of our future remarks, which cannot and ought not to be altogether extemporaneous.

THE SEASON is as favorable as the hopes of the farmer could anticipate. Fruit is not altogether so abundant as it was the last summer and autumn, but Grass and Grain are, generally speaking, very exuberant. Indian corn, likewise, promises fair, and there is a prospect that every rational expectation of the husbandman will be realized. It appears by the last American Farmer, that the southern section of the Union partakes with us in the bounties of indulgent Providence. A correspondent of *the Skinner*, under date of Wheatland, July 13, says:—“Our grain harvest is now nearly completed, and we are enabled to form a more accurate estimate of the results than heretofore, and it gives me great pleasure to inform you that the general crop far exceeds the expectations of the most sanguine calculation. In some instances the crop is as heavy as any I have ever seen in most I think it may be estimated at near an average. Our corn, millet, &c. present the most satisfactory promise, and, in fine, there is a prospect of the present year being far more prolific in the aggregate of agricultural products, than any which has been experienced for a long time.”

Mr. Erberton.—As you are anxious to contribute, not only to the wealth, but the health of farmers, I would suggest the utility of prescribing an effectual remedy for the cutaneous disorder, commonly termed *poison of the skin*. This irritating eruption is extremely prevalent among those now employed in hay-making, and is a small impediment to their important labors. It is thought to be caused by ivy and dog-wood which abound most in meadows. Washes of brine, fever-bush, &c. are frequently applied with little or no apparent success. I have lately heard that lime-water, employed as a wash has been found effectual.

Yours, respectfully

E. B. K.

FOREIGN.

Intelligence has been received from London as late as the 19th, and from the French army in Spain to the 13th of June. The French appear to be advancing without meeting with much opposition, aided and preceded by bands of Spanish royalists, who should seem to be active and numerous. The Spanish population appear not only to acquiesce, but exult in the domination of the invaders, and the Constitutionalists exhibit

cely the appearance of opposition. It may be that Constitutionalists are pursuing that system of politics which conquers by delay, but appearances at present are ominous to their cause, and almost preclude hope of their eventual success.

The Cortes continue to act with apparent resolution, announce their determination to conquer or perish. Other they will act the same part with the Cortes of Portugal, and make a great show of resistance in order to cover their dispersion, time only can determine. The Regency established under French auspices at Madrid, appears to be exercising almost undisputed authority over a great part of Spain. Prussia, Russia, Prussia, have recognized it as the legitimate government of the country, while the English minister is with the King and Cortes at Seville.

England subscriptions of money and arms have been raised to assist the Spanish cause, but the government appears to be determined not to depart from a neutral policy.

It is to be recollected that the Spanish news is distributed principally through French channels. Bell's Messenger, a London paper, says "The friends of Spain and Portugal cannot be too much on their guard against the devices of the common enemy, by its agents every political occurrence beyond the seas is distorted, if unfavorable to his views, and is twice grossly exaggerated before the public here in France are permitted to hear any thing about it." Another London editor says that he had been offered a large bribe to yield his columns to the dissemination of interested and deceptive statements. Still under allowances for one-sided statements and distorted misrepresentation, we shall not be able to form any conclusion favorable to the Spanish cause.

Ships Captured.—The United States' barges Gallier and Musquito, under the command of Lieut. Allen, and human, have succeeded in capturing near where Allen fell, a piratical schooner of 70 or 80 tons, and destroyed or made prisoners nearly or all her crew, amounting to about 40. When the schooner approached the piratical schooner, the crew of the latter leaped overboard, and attempted to swim ashore, but were pursued, and about twenty of them were taken by the captain of the District, and sent to Matanzas, where they remained in prison. The schooner was taken possession of by the barges. The commander, known by the name of *Little Devil*, killed in the action.

Shipwreck.—The brig Mechanic of New-York, has been lately burnt by pirates, and all on board murdered. The piratical schooner which committed this atrocious act was taken by two English cruisers, and thirteen of its crew were captured and conducted to prison.

Attack on the Patriots.—The attack was sudden and unexpected. About 200 of the Colombians are said to have killed and wounded. The remainder made good their retreat.

The United States' brig Enterprise.—On the 1st of this month, this vessel was cast away on Little Caracacas, and crew were all saved, and the rigging, stores and guns were recovered from the wreck.

DOMESTIC.

Hon. Smith Thompson has been appointed, by President, a Judge of the Supreme Court of the States for the second circuit, in the place of Livingston, deceased.

Rev. Heman Humphrey, of Pittsfield has been chosen President of the Collegiate Institute at Amherst, Mass. vice Rev. Dr. Moore, deceased.

John Meer, of Philadelphia, has discovered a new process, by chemical process, of hardening a soft argillaceous stone, of little use or value as it comes from the quarry, so as to give it any degree of hardness suitable for sharpening all the different instruments which require a very fine edge, such as razors, graters, surgical instruments, &c.

Fire.—The valuable two story Farm House in Montpelier, Vt. owned and occupied by C. C. & A. S. Wing, was consumed by fire on the 21st inst. The fire is supposed to have been communicated by sparks from the chimney falling on the roof. Most of the furniture was saved. The dwelling house, barns and out buildings belonging to Capt. Leonard Hodges, of Williston, (Vt.) were lately consumed by fire. The fire originated in an adjoining field, which had been set on fire, and the family having left the house for the purpose of extinguishing it, the building took fire in their absence, and was not discovered till it was too late to effect any thing more than the saving of a little furniture, and a few articles contained in the out buildings.

The Small Pox is said to be prevailing at Baker-field, Vt. to an alarming degree. One death has occurred, and the lives of two or three others are despaired of. The infection was communicated by a gentleman recently returned from Canada, to which a great number were exposed before the nature of the disease was known.

A man was lately discovered in Lynn woods, extended on the ground and perishing with hunger. He was unable to give any account of himself, had built a sort of a wigwam, was extremely emaciated, and had been missing about two months. He was removed to an almshouse, and it is thought that he may recover.

We hope to do some good by suggesting to those who might not otherwise think of it, the danger of suffering children to eat as freely as they choose of unripe fruits and vegetables. There is a great deal of this trash that can easily be got at, and while even grown people sometimes make themselves sick in this way, it should be recollected that children have more fondness for these things, and little if any judgment in the use of them.—*Conn. Mirror.*

The Philadelphia Society for the encouragement of Agriculture, has awarded to Mr. Jonathan Nichols of this town, a medal and twenty dollars in cash, being the highest premium it can bestow, for the invention of his Spring Carriage Seat.—*Progr. Jour.*

Messrs. Dyers & Co. have completed their Currant Vintage. They gathered more than eight hundred bushels of currants, and have made fifteen thousand gallons of wine. Four thousand dollars worth of sugar was melted down in the process, and two hundred dollars paid to children for gathering the fruit, besides other large expenditures for labor.—*Ibid.*

A very singular fact occurred in Manchester a few days since. As Mr. Samuel Cheever was at work in his field, his attention was arrested at the sight of a number of dung-hill fowls, with heads erect and wings extended, standing in a circular manner. On going near to ascertain the cause, he saw a large black Snake of 5 feet in length, within the circle, and his squamous head elevated 7 or 8 inches above the surface of the earth, while his posterior parts remained in a spiral form. And so complete was the fascination, that Mr. C. was under the necessity of getting a pole to disperse the fowls, in order that he might kill the snake, in which he happily succeeded.

The Serpent, which had power over our mother Eve, hath power also over the beasts of the field, and the fowls of the air!—*Essex Register.*

By a recent decision of the Supreme Judicial Court it has been decided that Banks are liable to pay their note when one half is presented by the owner, the other being lost.

Mr. John Prall, Jr. of Prallsville, in this county, says the Trenton, N. J. American, has this season cut and gathered, from two and a half acres of meadow, nine tons of Timothy hay. One of the stalks measured more than five feet in height; and the whole averaged more than four feet.

Three highwaymen have been arrested in the neighborhood of Albany, having in their possession pistols, gunpowder, knives, and all the necessary implements for their foul profession. Two belonged to Philadelphia, and the other a lad, only 16 years of age, belonged to New York.

As some men were lately digging a cellar in Lynn, they found a human skeleton, apparently that of an Indian, who must have been buried many years ago. It was on one side, with the feet and legs drawn up. The bones were very large, and beside them were found two large clam-shells, probably intended for the deceased to eat his soup, on his journey to the land of spirits.

An insane man named Freeland, entered a boat in New York on the 21th July, and proceeded to the middle of the New York river, where he cut his throat in a most shocking manner. Every attempt was made to save him, but proved fruitless.

The amount of capital which may be invested in Manufacturing Incorporations granted the last session of the Legislature alone, in this State, is five million of dollars. The Dover Company employ one million; the Nashua Company, one million; Somersworth, half a million; Jaffrey and Chesterfield \$300,000.

Kenneb. Sentinel.

It is stated in the Kingston (Jamaica) papers, on the authority of an intelligent gentleman from Cuba, that in consequence of the continuance of extreme dry weather for many months in Cuba, that the loss in cattle and in horses is estimated at a million of dollars.

Rural Sounds as well as Sights delightful.

Nor rural sights alone, but rural sounds
 Exhilarate the spirit, and restore
 The tone of languid Nature. Mighty winds,
 That sweep the skirt of some far-spreading wood
 Of ancient growth, make music not unlike
 The dash of ocean on its winding shore,
 And lull the spirit while they fill the mind,
 Unnumber'd branches waving in the blast,
 And all their leaves fast fluttering all at once.
 Nor less composure waits upon the roar
 Of distant floods, or on the softer voice
 Of neighbouring fountain, or of rills that slip
 Through the cleft rock, and chiming as they fall
 Upon loose pebbles, lose themselves at length
 In matted grass, that with a livelier green
 Betrays the secret of their silent course.
 Nature inanimate employs sweet sounds,
 But animated nature sweeter still,
 To soothe and satisfy the human ear.
 Ten thousand warblers cheer the day, and one
 The live-long night: nor these alone, whose notes
 Nice-finger'd art must emulate in vain,
 But cawing rooks, and kites that swim sublime
 In still repeated circles, screaming loud,
 The jay, the pyc, and even the boding owl
 That haills the rising moon, have charms for me.
 Sounds inharmonious in themselves and harsh,
 Yet heard in scenes where peace for ever reigns.
 And only there, please highly for their sake.

COWPER.

From the Upper Canada Weekly Register.

NATURAL HISTORY.

Sir,—I beg leave to send you the following account of a very extraordinary phenomenon which lately occurred in the waters of Lake Erie, which you are at liberty to use in any way you think proper. I am, &c.

A. H. BURWELL.

Port Talbot, June 20, 1823.

On or about the 30th of May last, a little after sunset, lake Erie was observed to take a sudden and extraordinary rise, the weather being fine and clear, and the lake calm and smooth. It was principally noticed at the mouths of Otter and Kettle creeks, which are 20 miles apart. At Otter Creek it came in without the least previous intimation, in a swell of nine feet perpendicular height, as was afterwards ascertained, rushed violently up the channel, drove a schooner of 35 tons burthen from her moorings, threw her upon high ground, and rolled over the ordinary beach into the woods, completely inundating all the adjacent flats. This was followed by two others of equal height, which caused the creek to retrograde a mile and a half, and to overflow its banks where water was never before seen by seven or eight feet. The noise occasioned by its rushing with such rapidity along the winding channel, was truly astonishing. It was witnessed by a number of persons.

At Kettle creek several men were drawing a fish net in the lake, when suddenly they saw the water coming upon them in the manner above mentioned; and, letting go their net, they ran for their lives. The swell overtook them before they could reach the high bank, and swept them forward with great force; but, being expert swimmers, they escaped unhurt. The man who was in the skiff, pulling in the sea line, was drove with it a considerable distance over the

flat, and grounded upon a small eminence until the water subsided. There were three successive swells as at Otter creek, and the effects up the creek were the same, with this difference, the water only rose seven feet. In both cases, the lake, after the three swells had spent their force, gradually subsided, and in about twenty minutes was at its usual height and tranquillity. It was observed at other places along the shore, but the high steep banks did not admit of the same observation. In all however, there was a general correspondence as to the height of the rise.

Conjecture will doubtless be awake as to the cause of this most remarkable phenomenon: but it must only be conjectured, for it was unattended with any circumstance that could remotely hint at a probable cause.—But such was the fact, and it must furnish its own comment.

REINDEER IN GREAT BRITAIN.

Mr. Bullock's attempt to introduce Reindeer into Great Britain is likely to be completely successful. A herd of these fine animals is now in Ireland, on the lands of Sir W. M'Mahon; and in Scotland, on the hills to the west of Edinburgh, a herd has not only been naturalized on the soil and food, but the females have produced their young, and are thriving as well as if they were in Norway. Some of the Wapiti, or gigantic stag of the Missouri, have also been imported into Scotland. These animals are of the size of horses, and can be broken for harness, in which their speed must be prodigious.

[U. S. Gazette.

PRACTICAL ADVICE.

Fill up your time so fully with useful employments, as to have little leisure for pursuits of a doubtful character. Endeavour further to acquire such a strong sense of duty, such a taste for contemplations of a higher order, and such well arranged habits of sacred study and devotion, as may supersede the temptation to devote to idle, if not injurious amusement, moments which may be so much more profitably given to the great concern of preparation for another world. Keep in mind the claims which your family, your friends and society, have upon your hours of retirement; and the importance of so employing those hours, be they few or many, that both your mind and your body may be refreshed for the returning duties of each successive day. And, lastly, guard against habits of idle curiosity, and be not ashamed to own that there are many things with which neither your time nor your taste permit you to be acquainted, and least of all with every new tale that happens to be the subject of popular conversation."

Anecdote of the late Dr. Hutton, connected with his extraordinary advancement.—Dr. Hutton was originally a common workman in a coal mine in the north of England, and having in the use of his pickaxe wounded his arm, he was disabled from pursuing his humble labor. In order to gain an honest livelihood, he applied himself to writing and arithmetic, and subsequently set up a little school. Hexam Bridge, by some accident fell down, and Dr. Hutton, then an obscure country schoolmaster, wrote a long paper, recommending a model for the new bridge, which attracted great attention in that part of the coun-

try, and was well believed adopted. Subsequent advertisement appeared in the London paper inviting candidates for the office of Professor Mathematics in Woolwich Academy, and soliciting at the same time testimonials of their respective claims. Two persons were selected, the result of the examination, by scientific men and these two were Dr. Hutton, and the celebrated Dr. Maskeline, late Astronomer Royal. The umpires, who had scrupulously examined pretensions of each, declared that there was very little superiority between these successful candidates, but if there was a preference Hutton was entitled to it.—Hutton was totally unfringed, and had not been seen at the time by examiners.

GARRICK AND FOOTE.

The success of Garrick's Stratford Jubilee which ran ninety nights in one season, so annoyed Foote, that he was going to burlesque it by a mock procession. A man dressed in Garrick was to be introduced as the principal character, and some one was to address him in his own Jubilee lines—

"A nation's taste depends on you,
 "Perhaps a nation's virtue too."

To which he was to make answer only by clapping his arms like the wings of a cock, crowing out—

"Cock-a-doodle doo!"

Garrick hearing of this, was so much amused, that he got a nobleman to persuade Foote to abandon his mirth-moving design.

Some of our journals have lately repeated Tom Sheridan's facetious equivocal to his brother when he advised him to take a wife—have no objection, Sir, whose wife shall I take. An equivalent to, if not the original of which we remember to be of some standing in Warwickshire. Sir —, a justice of the peace had frequently had before him, at the sabbath parish, farmer B—, whose love of trigue often brought him into paternal scrap. One day, while his worship sat with my lord it was announced that the worthy farmer charge of the constable, attended for a hearing touching one of his usual misdoings. My lord was requested to leave the room during the amination; and on going away met the culprit. "Ah! John," said she, "why do you come so with the girls—why don't you get a wife?" Poor John scratched his head apologetically and replied, "So I does, ma lady, sometimes but then their husbands are so dommed mad

The Strawberry.—It is a fact, though not generally known, that the common strawberry is a natural triforce; and that its juice, without any previous preparation whatever, dissolves the tartarous incrust on the teeth, and makes the breath sweet & agreeable.

TERMS OF THE FARMER.

(P) Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but if who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

(P) No paper will be discontinued (unless at discretion of the Publisher) until arrearages are paid.

(P) Agents who procure seven subscribers, and become responsible for the payment, will be entitled copy gratis, and in the same proportion for a larger number.

No. 2.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

It is supposed that by this time you have completed your haying, and finished the former harvest, and perhaps have leisure and occasion to attend to the process of

Drainage, or freeing your land from superfluous moisture.—This is an operation of great importance in agriculture, though comparatively speaking, it has not so strong claims to attention in the United States, where labor is dear, and land is cheap, as in older and more populous countries, where it is necessary that "every rood of ground maintain its man." It is not often advisable to neglect, or half cultivate arid lands, for the sake of undertaking extensive projects of draining bogs and morasses, but it sometimes happens that labor, skillfully directed, can in no way be so profitably bestowed as in drawing off the superabundant water from a soil which is rendered unproductive by an excess of that element. A piece of ground, which is made useless, and unhealthily, by too much water, may be situated near a farmer's house or barn; or it may be well for the sake of health, safety to his cattle, or for improving a prospect from his place of residence, to drain some particular spots, although there could be no probability that the products, or the additional value of the soil itself will ever compensate for the expense of such draining.

We shall not attempt to give any very elaborate remarks on this subject, nor to enter at all into what may be called the philosophy of draining. We shall say nothing under this head relative to the different strata or layers of substances of which the earth is composed, and of cracks or fissures between them, which form deep caves or reservoirs of water, as the case may be. What has already been published respecting Mr. Elkington's improvements in draining, in our paper, vol. i, p. 403, will suffice, as it relates to this branch of the subject, for practical cultivators. Those who wish for a thorough knowledge of the principles of the art of draining, must not only attend to geology and mineralogy, study a number of books written on these topics, but must view the operations of nature in hilly countries, and trace the signs of drainage from mountain to valley, follow underground brooks and rivulets by appearances on the ground, which indicate their course; and then by viewing the shape and materials of the earth's surface what is the probable structure of its interior.

Drains used in farming are of two kinds, open and covered. Drains should be of a size and depth proportioned to the extent of the swamp, and the probable quantity of water for which they are designed to be channels. They should generally be carried through the lowest and wettest part of the soil, although it should be necessary, in order to effect that purpose, to depart from straight lines. Open drains sometimes answer the double purpose of conveying superfluous water, and of inclosing fields. They make a hazardous and inconvenient improvement without the addition of a bank, hedge or fence. The Farmer's Assistant says, "when

a ditch is made for a fence, it ought to be four feet wide at the top, one or less at the bottom, and about two and an half deep; with the earth all thrown out on one side, and banked up as high as possible." Sir John Sinclair states that "it is a general rule regarding open drains, with a view of giving sufficient slope and stability to their sides, that the width at top should be three times as much as that which is necessary at the bottom, and in the case of peat mosses or soft soils, it should be such as to allow the water to run off without stagnation, but not with so rapid a motion as to injure the bottom."

But before you attempt to drain a piece of land, it will be well not only to calculate the cost, but to ascertain the nature of the soil which it is proposed to render fit for cultivation. If the subsoil or under layer be clay, the swamp may be worth draining, though there should be no more than six inches of black soil or mud over it, for the clay and the mud mixed will make a fertile soil. But if the sub-soil or under stratum be gravel or white sand, it will not, in common cases, be best to undertake draining unless the depth of black mud be as much as from fifteen to eighteen inches deep; for the soil will settle after draining and be less deep than it was before. But the situation of the land to be drained may authorize some variation from these general rules.

The manner of draining a swamp is as follows: Beginning at the outlet, pass a large ditch through it, so as mostly to cut the lowest parts. Then make another ditch quite round it, near to the border, to cut off the springs which come from the upland, and to receive the water that runs down from the hills upon the surface, in great rains. These ditches should be larger or smaller, in some proportion to the size of the swamp, the shape and size of the hills which surround it, and other circumstances, which might tend to greater or less quantities of water's being occasionally or generally led to the ditches. If the swamp be large it may be necessary that some smaller cross drains should be cut in several of the lowest parts. The bottom of the main ditches, when the soil is not of an extraordinary depth, must be lower than the bottom of the loose soil; otherwise the soil will never become sufficiently dry and firm.*

It is said by Sir John Sinclair (Code of Agriculture, page 182) that "in all drains, it is a rule to begin at the lowest place, and to work upwards, by which the water will always pass from the workmen and point out the level.—This enables the laborers also to work in coarse weather, and prevents their being interrupted by wet, so early in the season as otherwise might happen."

The mud and other materials, which are dug out of a ditch or drain should not be suffered to lie in heaps or banks by the side of the ditch, but should be spread as equally as possible over the surface of the drained land. In this way the matter taken from the ditches will tend to level the surface of the swamp, will, perhaps,

serve in some measure for manure, and will not present any impediment to the passage of the water to the ditches. In some cases it may be advisable to transport the earth which is taken from the ditches, to the farm-yard, or the hog-pen, to form a part of that layer, which good farmers generally spread over those places in autumn to imbibe liquid manure or make into compost with dung. In many instances, we are told, that the earth thus dug out of ditches is thought to be worth enough to pay for the expense of digging the ditches.

The American editor of Sir John Sinclair's Code of Agriculture, has the following among other judicious remarks on this important subject. "The most expeditious, effectual, and economical mode of making a drain would undoubtedly be to use oxen, and a scraper or ox-shovel, as it is sometimes called; an instrument well known in this country in the making of roads. In some cases this mode might not answer, as in very miry grounds, and lands just cleared of timber. But where lands are very miry, if the process is begun at the outlet of the water, and there indeed it ought always to be begun, the next adjoining portion will generally be made so dry as to allow being trodden upon in a proper season; and in this way a drain may by degrees be carried on towards the centre. In nineteen cases out of twenty, drains may be probably effected in this mode. Where the ground will admit of it, two men and a boy, and two yoke of oxen, will accomplish more business of this sort in a day, than half a dozen men in the same time with only spades and shovels. Wherever the labor of cattle can be substituted in this country, for human labor, policy requires it to be done. The surface of wet and miry lands is usually full of inequalities: if a scraper is employed in draining them, the earth taken from the drain is easily landed in any hollow spot which needs to be filled; and if there are no such hollows, or they have already been filled, the earth may be spread over the surface in such a manner as to do the most good. If the earth is not wanted for other purposes, it is recommended to drop and spread it, if practicable, in such a manner as to leave the general surface of the land sloping towards the drain, that the water may the more readily incline towards it and pass off. At some distance below the surface in peat grounds, there is usually found a hard stratum of earth, called in the common language of our farmers *hard-pan*. The hard-pan, if ploughed into, scraped out, and spread on the surface, would greatly improve the texture of such soils. This furnishes another argument in favor of using a scraper in draining, for in no other way can the upper earth taken out of the drains be so cheaply removed, and put on the adjoining; nor in any other way can the hard-pan be so easily broken up and carried off, nor in any other way, oftentimes, can suitable earth be so well obtained for the purpose of spreading it over the surface with a view to improve the texture of the soil. If the object be to pile the earth from the drains into heaps with a view to composts, this purpose is completely accomplished by means of the scraper."

* See Deane's New England Farmer, Art. DRAIN.

Even in cases where no outlet can be obtained, land may be drained to some effect by digging a ditch of considerable breadth and depth, which will serve as a reservoir for the water, and the earth taken from the ditch will, if properly spread, not only make room for the superfluous water, but elevate the surface of the soil. In this way the water may be separated from the land to pretty good purpose. But it is always best if possible to obtain an outlet, which it is desirable may be so low that the water in the ditches may have some motion, lest its stagnation cause unhealthy exhalations.

The preceding remarks are applicable chiefly to draining on a large scale. The following observations taken from an excellent "*Essay on the Principles and Practice of Rural Economy*," by G. W. FEATHERSTONHAUGH, Esq. may perhaps, more frequently apply to practical purposes, than those which recommend processes more laborious and expensive. "In ordinary situations where there are no obstructions above, and the declivity easy, the task is not great nor very expensive; a cut two feet wide made in the right situation, three feet deep, and narrowed to a foot at the bottom, is sufficient to lay the land dry for a great distance, if it is carefully cleaned out every fall; for the distant water will in twelve months make itself small channels beneath the surface of the cut, which will be pressed up by continual percolation: by this simple operation, lands which have never produced any thing are made to produce heavy crops of turnips or grain, and become productive hereafter: the expense, even when the labor is to be paid for, is nothing compared to the benefit. A laborer may easily make three rods a day, which at fifteen dollars per month for board and wages, is about eighteen cents a rod. A cut of this description, with smaller ones leading to it if necessary, is amply sufficient, and will stand to all effective purposes in the place of those expensive methods practised in Europe. If it be an extensive bottom and proper for permanent meadow, the cut may be enlarged to any width at the same expense, by varying the method. The plough and the scraper should be used instead of the spade, taking care to finish the banks with a neat slope to the bottom, by the spade and rake, and sowing a few grass seeds upon it, at a proper season to take root before the freshets come on. If this be done in a proper manner, the grass will grow as well on the slopes and the bottom as on the surface of the meadow, and be cut with as much ease and advantage. Wide drains of this description seldom want cleaning out; the sod prevents the soil washing in. A cut of this description, which I made eight years ago in a piece of interval of 200 acres, has not wanted cleaning out to this moment."

An English writer in remarking on this subject says in substance, that a swamp, which is covered with moss may be injured by draining it too much—that his crops were best when the surface of water in the surrounding ditches was not more than three feet lower than the meadow—that it will be a great advantage to the improved moss-ground if the farmer is able to flood it at proper times, by means of a dam and gate at the outlet. This will greatly add to the fertility of the land, which is drained, but care must be taken not to let the water remain on the ground too long a time, because, though there will be no danger of its re-converting the

soil into a bog, so long as there are channels to carry it off, it will be apt to chill and injure the plants.

If a swamp is overrun with bushes, a dam at the outlet, by means of which it may be flooded, will, perhaps, present the best mode of subduing them, which may be effected by flooding in two or three summers. It will besides afford a good method of enriching the soil. The Complete Farmer says "first drain the land, and if there be any heath or turf on it, burn that off, and shape the surface over. Then make a dam at the lowest part, and a sluice, and work the water upon it through the winter. The mud which comes with the land flood will bring a fine sward over it in two or three years, and be afterwards a yearly manure; so that it will bear annual cutting, and besides be good pasture for cattle after the sward has become strong enough to bear them.

There are some drained meadows in the neighborhood of Boston which have dams at their outlets, by means of which the water may be made to cover the surface of the meadow, or stand at such height in the ditches as may be thought necessary to communicate a proper degree of moisture to the soil. In a hot and dry season the water is so far purposely obstructed at the outlet as to stand in the drains within two or three feet of the surface of the meadow. The water generally penetrates every part of the soil in the meadow, as high as the level at which it stands in the ditch, and some degree of moisture is drawn by the heat of the sun, (provided the soil be tolerably open and porous) quite to the top of the ground. This ascent of moisture from the wet ground below is effected by the same principle which causes oil or tallow to rise in the wick of a lighted lamp or candle. If a soil is naturally too wet, by causing water to stand in its immediate vicinity within two or three perpendicular feet of its surface, you will increase the evil more than most people would be aware of; and if a soil is naturally too dry, or is suffering in consequence of a dry season, letting water into ditches or channels two or three or more feet below the top of the ground will give moisture to the whole mass. Thus springs which flow under, but near the surface of the ground, may often be traced by the verdure of the herbage above them; and the banks of rivulets bear aquatic plants and exhibit other marks of moisture for several feet above the ordinary level of the water. A knowledge of this principle may sometimes be of use to gardeners, and lead to perhaps the best way of watering delicate plants, viz. instead of applying water directly to the roots, let it be poured plentifully into small trenches between or near the rows of the plants to be watered, and it will percolate slowly through the thirsty earth, and in its passage become warmed, imbued perhaps, with particles of manure, and thus answer a better purpose than cold water from a well and a watering pot, applied directly to the plants, at the risk of displacing some of the soil and deranging the economy of the small and fibrous roots.

To destroy Crickets.—Mix some roasted apple with a little white arsenic powdered, and put a little of this mixture into the holes or cracks in which the crickets are; they will eat of it and perish.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR.—If you think the following account of the effects resulting from experiments made with Plaster of Paris, can be of any use to the public, you have the liberty of publishing it in your useful paper.

About eighteen years ago I purchased half a bushel of Plaster, with a view of trying it on my land. A part of it I sowed on my mowing some of it I put on my corn, and a small quantity was left which I put into a box and set away, having very little faith in its utility, and having some fears lest it would eventually injure the land on which it was used.

I could not perceive that it had any effect on my corn, and very little, if any, on my grass and of course I determined to make use of no more of it.

In the spring of 1813 I wanted the box in which my plaster had been kept for seven years for another use. I thought to myself what shall I do with my plaster, considering it to be good for nothing. I thought I would put it into the road, but at length the thought occurred to me it might possibly do some good, and as there was but a small quantity of it, it could do but very little damage. I sowed it upon a piece of dry grass land which had been mowed for many years, but which produced so little as to scarcely pay the expense of getting the hay. I sowed my plaster about the first of May, and it was but a short time before its effects were clearly to be seen. When I cut my grass I could see exactly where the plaster was sown; it was mostly clover, being thick and very much like rowen. I had a second crop almost as large as the first. The second year the produce was about as good as the first, and the third about half as good as the first and second years, and the fourth the same as it was before any plaster was sowed.

I now make use of plaster on this piece of ground with the same effect as at first. It produced this year a fine crop of grass, principally clover, and now promises fair for a second crop. The beneficial effects of plaster on pasture land are very great. I have used it in this way eight or ten years. I sow it on the same piece of ground every second year. Five or six pecks to an acre I think sufficient. My pasturing is essentially improved and produces nearly double the quantity of feed than it formerly did. A part of my pasture formerly produced little else than bushes, which I frequently cut, but could not exterminate them, and the land being so moist and rocky as to forbid the use of the plough. This part of my pasture now has quite a new appearance. Since I have commenced sowing plaster upon it I have cut the bushes twice, and they are almost entirely gone. The grass, particularly white clover, grows luxuriantly.

In 1817 I sowed a piece of ground with flax and on two thirds of it I sowed plaster. The flax on the third part on which I sowed no plaster was not so large by one quarter as the other.

In 1818 I planted a field with potatoes, and manured one half of it, putting a good shovelful of manure in each hill in every second row through the field. The other half I put a spoonful of plaster in each hill. When I dug my potatoes I found the produce of the plastered row to be full equal to those that were manured.

In 1819 I planted a dry gravelly piece of land

with potatoes, which had become so barren as to be considered almost worthless. I put a spoonful of plaster in each hill, hoed them once, and had an excellent crop of potatoes.

I have now an acre of potatoes growing which I plastered, which look remarkably well and promising.

A FARMER.

Worcester, August 1, 1823.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—The following is founded on fact, and with a little variation, is literally true. Mr. A. and Mr. B. are two farmers living only eighty rods distant from each other. Their farms each contain about one hundred and twenty acres of land, being of about equal value.

Mr. A. manages his farm so as to summer and winter twenty head of cattle and keep them well, and always has a ton or two of good hay left in the spring. He raises two hundred bushels of corn in a year and about the same quantity of English grain. He and his two sons, the one twenty and the other fourteen years of age, perform all the work on the farm, as they hold it a fundamental principle not to hire any labor, unless something special and unforeseen should render it absolutely necessary. This work is always done in season, and much time is gained, which is spent in building stone wall and making other valuable improvements on the farm. He never makes any bluster about his business, but always keeps a steady course, beginning early in the morning and finishing his work in season at night. He says that he chooses to do his own work rather than to hire it done, for if he does it himself it will be done as he wishes to have it, but if he hires it done he will have to pay for, and there is the expense of boarding, which is something.

He says he is obliged to study economy that he may keep along and gain a little. He will not run into debt, unless necessity compels him to do so, as he thinks it is better for him to do without things that would be convenient, but can be dispensed with, than to buy them on trust, and pay by and be under the necessity of selling a yoke of oxen, or a piece of land, to pay his debts. He and his sons drink no ardent spirit on any occasion whatever, for they have learned by experience that they can perform more work and be more robust and hearty without spirit than with it, and by abstaining from the use of it they are able enough at least to pay all their taxes, beside the hazard of consequences arising from the danger and force of habit. Thus by prudence and economy he is able to meet all his demands, contribute liberally to the various benevolent objects of the day, and add something to his permanent fund besides.

Mr. B. conducts business in a very different manner. He has as much help of his own as Mr. A., yet his work is always driving him so that he is compelled to hire much extra labor, in order to keep business along. He raises no more grain nor cuts so much hay, nor gets done so soon as Mr. A. He makes no essential improvements on his farm, for he says that he can make more by working out with his team than he can to build stone wall and subdue his rough land. He is considered a temperate man, but it costs him more for ardent spirits than it does to pay his taxes. He says that he cannot work in hot weather, nor does he want his men

to work without rum. He is some in debt, and says he cannot bring both ends of the year together, yet he will not deprive himself or his family of the conveniences of life on that account. If himself or his family want any thing which they have not he will buy it and pay for it when he can; so that instead of lessening his debts he is continually adding thereto, and according to the course of things he will sooner or later be obliged to sell a part of his farm to satisfy the demands of his creditors.

W.

From the Massachusetts Agricultural Repository.

James Ombrosi, Esq. consul of the United States at Florence, has sent to the Massachusetts Agricultural Society, through William Little, Esq. of Boston, a few pounds of a grass seed, which he calls *Erba Medica*, and which he says is cut in Tuscany five or six times a year, and is there considered particularly nutritious food for cows or horses. It is chopped up, or in some other way, mixed with hay for cattle. Mr. Ombrosi and Mr. Little will be pleased to accept the thanks of the society for their attention. The seed appears to us to be that of some species of *Trifolium*, evidently not the broad leaved clover of Flanders, which is on the whole considered the best by European cultivators.

The Flanders clover, however, in our seed stores, is sadly mixed with other varieties, and sometimes other species of clover. The seeds of the *Trifolium officinale*, melilot, or yellow Trefoil, are intermixed to so great an extent, that some fields which we have sown with red clover seed, bought as such in the shops, are now of a yellow color from the prevalence of the melilot. The worst of it is, that it is an increasing evil. Ten years since the melilot, or yellow clover, was so uncommon, that we examined it as a botanical novelty.

From the American Farmer.

PLANTATION OF TIMBER.

MR. SKINNER—Having lost my mother at an early age, I was sent to her parents, to receive that care which a widowed father could not bestow on my infancy; and being in the vicinity of the Valley Forge, in Chester county, I witnessed the destruction of the timber of that estate, and of several adjoining ones, by the continental army huddled there in the winter of 1777. Every tree was cut down, and all the fence rails taken, to shelter and warm those heroes, who, though unable to prevent Sir William Howe from entering Philadelphia, were willing to brave the inclemency of a winter season, badly clad and badly fed, to keep him prisoner there; so that the proprietors, unable to enclose their grounds immediately afterwards, and scarcely able to purchase fuel, considered themselves utterly ruined. The effect of their complaints remained impressed on my mind, until I went to Europe in 1791, and induced me, while there, to make particular enquiries how those old countries obtained continual supplies of an article so indispensable for domestic and manufacturing purposes.

I learned with astonishment, that there was not probably one single tree in England or France, but had grown from the stump of another tree, which had been planted by the hand of man; or was itself one of those identical monuments of human industry, patience and foresight in planting.

The planting of chestnuts, and most other tree seeds, was as familiar to many, as the planting of corn with us; and except the aquatics, which are grown from cuttings mostly, and the evergreens, whose little seed are put into beds and transplanted, is preserved very much in the same way, both objects requiring a preparation and protection well known to farmers. Of these, however, I have given some details to the Agricultural Society of this State, from a translation of a French treatise, and which they may one day give to the public. The want of timber will not be so much felt in the United States, whilst the increased population is spreading over the immense forests of the west, as to require a knowledge of the science, except as concerns those who are proprietors of grounds on the borders of fresh water streams which render the clearing unhealthy; or others, who have cleared, hilly, broken or stony grounds, fit for timber, and fit for nothing else. But the science of cutting to grow again, if it may be called a science, should be known to every farmer, planter or proprietor, because the weight and value of the article will not allow of much transportation; and the advantage of a second growth on the spot is superior to trees already grown at a distance, if all had means to spare to procure them. There is nothing mysterious, or difficult, or costly, in procuring the second growth of trees of the common kind, and in greater quantities than the first growth, as the experience of every iron master in the country has shown; and indeed, those very farmers about the Valley Forge, who had witnessed the cutting of the timber by the owners of that estate for years, and who were so much alarmed at their situation and prospects in 1773, were, on my return in 1799, abundantly supplied by wood of second growth, and as rich and contented as ever. Patience they found of necessity; observation of what had passed so completely under their eyes, was all that was wanted.

What is most essential here now, perhaps, is a disposition to look to futurity—to provide in time; but, I will add, from what I learned and saw abroad,

1. That the felling of trees is confined to the winter season; or rather, to that time in which the sap is under ground.
2. That every tree, young and old, on a certain space, is cut in the same season, for old dead stumps do not re-produce.
3. That they are cut as smooth and level with the ground as possible; and
4. That, while young, they are kept from the browsing of cattle.

Your very obedient servant,

THOMAS W. GRIFFITH.

Baltimore, July, 1823.

Superficial Observers.—There are some persons that never arrive at any deep, solid, or valuable knowledge, in any science, or business of life, because they are perpetually fluttering over the surface of things, in a curious or wandering search of infinite variety; ever hearing, reading, or asking after something new, but impatient of any labor to lay up and preserve the ideas they have gained; their souls may be compared to a looking-glass, that whosoever you turn it, it receives the images of all objects, but retains none.

From the Edinburgh Magazine.

ON THE INFLUENCE OF THE MOON UPON THE SEASONS.

Translated from a paper of Olbers, in "Annales de Chimie et de Physique." Février, 1822.

The moon acts upon the earth in a manner certain and demonstrable; for it enlightens our nights, it draws the earth a little from its elliptic orbit, it occasions a small oscillation in the earth's axis, it produces the flux and reflux of the sea, and an analogous but less motion in the atmosphere. But it has been the general opinion of mankind, from time immemorial, that besides these demonstrable effects, the moon according to its different phases, exercises a considerable influence upon the health of mankind, upon animals, upon vegetation, and on chemical operations. Experience alone can throw light upon this subject; for it is possible that the moon may have an influence upon our atmosphere, produced by the different forces of attraction which it exercises at different times—and also by its light. Long and well conducted experiments have completely refuted such hypotheses; they have proved that neither the lunar phases, nor the situation of the moon with respect to the sun and earth, have scarcely any influence upon the weather; for no fixed relation whatever can be discovered between them, notwithstanding the vast number of trials and observations which have been made for a great number of years. The result deduced from one series of meteorological observation, are always contradicted by another series: we cite, for example, Howard, who believed he had discovered that the barometer rose most frequently in the quadratures, and that its fall was most common in the syzygies. Cotte, on the contrary, to whom meteorology is so much indebted, and who commenced in order to confirm the remark of Howard, afterwards found by twenty years' observation, that the barometer was the highest at the time of the new moons, and lowest at the time of the full moons. Lalande and Lamarck have drawn from their observations the most opposite result, respecting the effects of the moon in her passage by the plane of the equator. But a decisive proof of the small influence of the moon, appears to me to result from this circumstance, that this influence, by whatever force it may be produced, known or unknown, ought to be the greatest possible between the tropics; however, in the equatorial regions, not a trace of it can be found. In these countries, the heat, the rain, the winds, &c. all depend on the distance of the sun from the zenith of the place, without any regard to the situation or the phases of the moon. We may be yet more convinced of the smallness of this influence, if we reflect that the most opposite weather, in different parts, takes place at the same instant of time, and consequently, under the same lunar phase. This fact is determined, with the greatest evidence, by the accounts of the weather which we receive from different places, during the time of an eclipse. M. Bode, for example, has collected the remarks made during the time of a solar eclipse which happened on the 18th Nov. 1816; where we perceive a strong mixture of good and bad weather, without any respect to order, spread, during this day, through a great part of Europe. Professor Brandes, having compared, with great labor, but in a very instructive manner, the variation

of the weather, which took place over a great part of the earth's surface, in 1783, found no relation between it and the lunar phases; and if a variation in the weather appeared to coincide with these phases in any one country, no variations, or opposite variations, would take place in other countries. The period of eighteen or nineteen years makes no discovery of any sensible analogy in the variations of the weather during the years equally distant from these intervals.

Some have pretended to have remarked sensible effects produced by the rising of the moon, and by her culmination; but the phenomena cited by them, either do not prove this influence, or are not accurate. Several of our mariners, also hold, that the full moon, when rising, dissipates the clouds; but this prejudice owes its origin to the circumstance, that the clouds commonly disappear during a tranquil evening, and consequently at the rising of the moon, according to a very just remark of M. Brandes. The pretended observation, that a storm cannot approach from the zenith, at the time of the full moon, contradicts itself, for the electric cloud which is at the horizon of one place is at the zenith of another place not many miles distant. But in asserting that the lunar influence upon the seasons is extremely weak, and that it is nearly lost among the other causes which produce a variation in the weather, we are not certain that the moon does not produce some little effect. Let us see what the theory seems to indicate. The moon and the sun produce, twice in twenty-four hours fifty minutes, a flux and reflux, both in the ocean and in the atmosphere; these motions vary with the phases of the moon; they are the strongest in the new and full moons, and the weakest in the first and last quarters. Let us suppose, for example, that the tides of the atmosphere produce a change of .0351 of an inch in the height of the barometer, in the syzygies; it will produce only half that variation in the quadratures. Now, though these effects are so weak, it is not impossible but that the strong tides at the new and full moon may dispose the atmosphere to receive considerable motion. We dare not therefore, declare as absolutely false, the observations which some philosophers pretend to have made, namely: that more storms happen at the time of a new and full moon, than at the quadratures. It is the same with respect to the passage of the moon through the equator, and through the perigee; at these times it may act as an exciting cause, although no violent motion be produced by it in the atmosphere.

The moon may also have an influence upon the variation of the weather, in an indirect manner; that is by the motion of the waters of the ocean, at least upon some coasts. It is true, in the open sea, the height of the tides never exceeds three or four feet; but upon the coasts, in bays, and narrow channels, the rise of the tides is much more considerable. At Brest, for example, it rises more than twenty feet, and at Bristol more than fifty. Ought not the motion of these large masses of water to occasion some variation in the atmosphere, especially as they appear to have a small influence on the electricity of the air? The inhabitants of the sea-coasts believe it to be a fact, that the changes in the weather, and the force and direction of the wind and clouds, depend on the tides. We may

here observe, that the tides of the ocean, and those of the atmosphere, do not happen at the same period. The air being easily moved, and not being hindered by any obstacle, instantly obeys the attractive force of the moon; but the waters of the ocean are more tardy in obeying this force. On this account, the atmospheric tides immediately follow the passage of the moon over the meridian; but high water, in the open sea, does not take place till three hours afterwards; and on coasts, and in bays, it happens still later. It is possible, then, that the mediate and immediate effects of the moon upon the atmosphere, in some places mutually destroy each other; and this is perhaps the cause why the astronomer Horsley, at Oxford, could not perceive, in the English observations, any relation between the weather and the phases of the moon; while Toaldo, at Padua, believed that he could distinguish the moon's influence in the observations made during fifty years at Polesina. Now, though I would not deny but that the results deduced from observations by Toaldo, might be partly true for the climate of Italy, I must still observe, that from the great number of exceptions to this rule, he was himself convinced that the lunar influence was extremely small. A series of experiments for many years, has convinced me, that in our climate, where the weather is subject to more considerable and more numerous variations, the rules of Toaldo are entirely wrong. For example, on the 7th Dec. 1813, the full moon coincided with the perigee, and two days after the moon had its greatest northern declination, so that, from the principles of Toaldo, the lunar influence ought to have been the greatest possible; but notwithstanding all this, there was not any sensible change in the weather. I believe, then, that I have demonstrated, that the influence of the moon upon the weather is so small, that it is totally lost among the infinite number of other forces and causes which change the equilibrium of our very moveable atmosphere. The influence of the moon upon the weather, and upon the atmosphere, being so insensible, we are entitled very much to suspect its pretended influence, either upon men, animals, or plants. In fact, it is all of it due to illusion and prejudice. It is evident the duration of the period of some phenomena exhibited by men in health, agrees only nearly, and never exactly, with the lunar revolutions; and that these phenomena show themselves under every phase of the moon, not only in persons of the same age, and of the same constitution, but also in the same individual. This alone is sufficient to show that the moon has no influence, and all modern physicians are agreed on this point.

I have little faith in the observation of Sanctorius; namely, that men in health gain one or two pounds in weight at the commencement of the month, and that they lose as much towards the end. In the same manner, observations made with the greatest care, have induced me to doubt very much the remark cited by the poet Lucilius, and often since repeated: namely, that lobsters, oysters, and other shell-fish, are fatter while the moon is on the increase, than when she is decreasing. A very little attention will convince us of the nullity of this assertion; especially if we can but credit the remarks made by the able physician, Robault. I have great confidence in the very careful experiments made

the celebrated agriculturists, Ladronecker, Reichard, and Hartenfels; also by great naturalists, Budon, and Reaumur; who have distinctly, that the increase or decrease of the moon has no influence, either upon the germination of seeds, or upon the increase of plants, or upon the rapidity of their development, or upon their quality. I have also much difficulty in believing, that the light of the moon produces a particular effect different from that of any other light. The experiments made in me, in 1783, by Athan. Cavallon, and repeated by Bertholon de Saint-Lazare, prove nothing respecting lunar light augmenting evaporation; the same manner I assert, that those of Weitz, de with potash at Lautenberg, prove nothing respecting the lunar rays drawing forth humidity. If, in South America and Batavia, they are such a dread of moon-light, I should attribute the pretended pernicious effects said to be produced, more to the humidity of the air, and the coldness of the nights, than to the effect of any influence of the moon. Bonitus observes the tetanus to take place at Java most frequently during the night, in the rainy season; he expressly remarked, that the two terrible diseases so frequent in the East Indies, namely the cholera morbus and dysentery, most frequently took place during the rainy months of summer. The celebrated Reil observes, that persons have become incapable of supporting daylight from having slept exposed to the light of the moon. I have, however, never heard from sailors any complaint of this kind. M. Reil asserts, that children sleep less tranquilly when the moon is on the increase. Having had experience on this subject, I cannot speak ideally as to the truth of it; but, in any case, I would explain it without having recourse to the influence of the moon. I should be glad to know if painters have really remarked that the moon has an effect upon their colors, as they have pretended that it has.* In a word, experience does not prove any particular influence of the moon's phases upon animal organization; the theory given by R. Mead is absolutely false. I can positively assert that I have always been attentive to this subject, with respect to persons, during the long time that I have practised medicine, and that I never perceived any relation between the courses of the moon and my patients, or between their symptoms and means of effecting cures. Neither have I marked any influence of the lunar phases, either on diseases caused by worms, or dropsy, or on even on epileptic diseases; I will, however deny, contrary to so many ancient observations, but that the moon may have some influence in particular diseases.

Among all the instruments we can employ, in order to detect natural agents, otherwise imperceptible, the most sensible, as Laplace has very properly observed, are the nerves, the sensibility of which is often increased by disease. It is means of the nerves that we can discover the sole electricity produced by the contact of metals; and it can only be owing to the extreme sensibility of the nerves, that some sick

Experiments made at the Royal Observatory at Paris, have proved that the light of the moon condenses a very powerful lens, had no effect whatever in changing chemical products, though very sensibly and equally affected by the light of the sun.

Note by the French Translator.

persons are able to perceive the influence of the moon in particular situations, that influence being so extremely small.

It may also be this circumstance, perhaps, which has discovered to physicians, that there is a relation between the lunar phases and the access of epilepsy and insanity. I dare not decide whether we are to explain in this manner the remarks made by Dickmerbrack and Remozini, respecting the pestilential fevers, which raged in the years 1636, 1692, 1693, and 1694. It could, however, be owing to nothing but accident, that so many persons affected with fever died, during the time of the lunar eclipse, which happened on the 21st of January, 1693. The influence of the moon upon the crisis of diseases, taught by Galen, and defended so long in the schools of medicine, is contradicted by experience, at least in Europe; and if Balfour be right, in asserting that there is a connexion between the tides and the access of endemic fevers in India, and that the crisis of fevers happens but at the moment when the lunar solar action begins to decrease, we can only so far agree with him, that this effect only takes place near the sea-coast. In general, we must read those authors, who refer so many things to the effects of the moon on diseases, with considerable distrust. It is here, as in many cases of reverie—we only see it when we believe it. A belief in this influence can only deceive the observer, who, otherwise fond of truth, shares this belief with the sick persons; and thus it is that hope and fear excite in the imagination effects to which the moon does not in any way contribute. Thus, also, it was in former times. People in general were afraid of eclipses of the sun and moon, and believed that these phenomena exercised certain pernicious influences over sick persons, and persons possessed of weak nerves; now, absolutely no sick person perceives the effect, and the physicians pay no attention to it.

Leghorn Hats.—The common redtop grass that grows in our meadows, is superior in durability and color, to the leghorn straw. This is about the time to gather it. It may be selected by handfuls by following after the mowers, before the grass is shaken out. To bleach it requires a very simple process: Scald and dry the grass two or three times, which takes out the green color—then whiten it still further if you please, by placing it in a tub or barrel, in such a manner as to expose it to the fumes of brimstone; or braid it and then fumigate it, as the milliners do their leghorn bonnets. When we consider that it costs the price of six or eight weeks labor of a girl to purchase a leghorn hat, is it not well worth the while for farmers to let their boys select grass for their sisters and others to braid. Even the largest of the grass makes hats of finer quality than gentlemen commonly wear. More than a million of dollars has been paid for leghorn bonnets within the last year.

Bennington Gazette.

Corn.—To procure a good crop of corn, we would recommend to the farmer to put a good coat of plaster, say about $\frac{1}{2}$ bushel to the acre, on meadow land, soon after mowing, and turn in the crop of rowen, when grown. In the spring bush it, so as not to disturb the sod—cross-furrow, and dung it in the hill. By this method we believe the worm will be less likely to in-

jure it than when turned over in the spring; the growth will effect it less; and the corn will be earlier. By this method you have your annual crops, and the land seems to be restored to its original state. This plan was taken by a neighbor of ours, who has unquestionably the best corn in the town, if not in the county.—*ibid.*

COMMUNICATED FOR THE NEW ENGLAND FARMER.

MEDICAL SCHOOL AT BOSTON.

The Medical Faculty of Harvard University give notice, that their lectures at the Massachusetts Medical College in Boston will begin on the third Wednesday in November, and be continued daily until the usual termination of the course.

It is presumed that the means, now possessed by this school for promoting and facilitating the acquirement of medical knowledge in all its branches, are equal to those offered by any American college, and commensurate with the advances made by society in the other departments of useful learning. As auxiliary to the several courses of medical instruction, the school is amply provided with apparatus, collections, and opportunities for practical demonstration; which, if aided by industry on the part of the student, are calculated to afford him the same kind of information, as that for which the hospitals and seminaries of Europe are usually visited. These auxiliary advantages consist in a large and select medical library; a cabinet of a thousand anatomical preparations; an ample and well furnished chemical laboratory; a collection of specimens of the materia medica; a suit of models and specimens for illustrating the principles and operations of obstetrics; a course of recent dissections, both public by the professor, and private by the students themselves; and lastly, an opportunity of acquiring practically medical and surgical knowledge at the Massachusetts General Hospital.

The following courses of lectures begin and terminate at the periods which have been specified.

Anatomy and Surgery, by Dr. Warren, fee \$20.

Chemistry, by Dr. Gorham, fee \$15.

Midwifery and Jurisprudence, by Dr. Channing, fee \$10.

Materia Medica, by Dr. Bigelow, fee \$10.

Theory and Practice of Physic, by Dr. Jackson, fee \$15.

These constitute the regular course of medical instruction preparatory to a medical degree. Students, who choose, have the additional opportunity in the spring season to attend lectures at Cambridge on Mineralogy, Botany, Natural Philosophy, and Philosophy applied to the Arts, as well as on various departments of literature.

As the Massachusetts General Hospital has not been completed so as to be accessible to medical students until within the two last seasons, it may be proper give some account of the opportunity it affords for practical instruction to students during their residence in the city. The wards of the medical departments have always furnished a succession of interesting cases, both acute and chronic, which have been under the care of the professor of the theory and practice of physic. Regular clinical lectures during the winter are given upon these cases, and students are admitted to the patients so far as to become experimentally conversant with the symptoms

of their diseases, the progressive changes which take place, and the operation and influence of medicinal agents.

As is common in large establishments of the kind, many patients resort to the General Hospital to undergo surgical operations, rendered necessary by accident or disease. No other kind of institution affords equal opportunities for acquiring a practical acquaintance with operative surgery. Not only the operations themselves, but the treatment of the cases preparatory and consequent to the operation, and the progress and management of convalescence, may be here studied and observed. The superior conveniences which a well arranged hospital affords for the accommodation of the sick, renders this institution a resort, not only of the poorer class, among whom in a large city, accidents are of frequent occurrence; but of other individuals from a distance, who come with the expectation of relief from chronic maladies requiring surgical treatment.

The following is a record of surgical cases, and of operations performed in the Massachusetts Hospital, by the Professor of Anatomy and Surgery, during twenty months, from the opening of the building in Sept. 1821, to June 1823.

1821.	Sept.	21.	Operation for Prolapsus ani.
	Oct.	18.	Lithotomy.
	"	23.	Operation for Popliteal Aneurism.
	"	25.	Operation of Fistula in ano.
	Nov.	10.	Fractured leg.
	Dec.	9.	Dislocation of the hip in the ischiatic notch.
1822.	Jan.	6.	Fracture of the thigh.
	"	"	Compound fracture of the leg.
	"	30.	Removal of a portion of the tibia.
	Feb.	5.	Amputation of the leg.
	"	19.	Operation for phymosis.
	"	"	Removal of diseased toes.
	March	9.	Fractured leg.
	April	22.	Compound comminuted fracture of leg.
	"	24.	Extirpation of tumour from the breast.
	June	8.	Comminuted fracture of the Os humeri.
	July	17.	Amputation of the breast.
	August	2.	Compound fracture of both patellae.
	"	30.	Removal of foreign substance from the globe of the eye.
	Sept.	20.	Amputation of the breast.
	Oct.	12.	Extirpation of the parotid gland.
	"	"	Operation for prolapsus ani.
	"	23.	Operation for Fistula in ano.
	Nov.	23.	Operation for Cataract.
	"	26.	Operation for Necrosis.
	"	"	Removing tumour from the foot.
	Dec.	20.	Operation for artificial pupil.
1823.	Jan.	15.	Removing tumour from the side.
	Feb.	5.	Removing fragments of rib.
	"	12.	Operation for Cataract.
	"	18.	Operation for ligular aneurism, the iliac artery tied.
	"	"	Facial nerve divided for tic douloureux.
	"	25.	Operation for phymosis.
	"	"	Laying open a fistulous ulcer over the ribs.
	"	26.	Inferior maxillary nerve divided for tic douloureux.
	March	6.	Fractured leg.
	"	"	Operation for Cataract.
	April	4.	Operation for Cataract.
	"	29.	Operation for Cataract.
	May	26.	Operation for Necrosis.
	"	21.	Fracture of the thigh.
	"	26.	Operation for Cataract.
	June	9.	Operation for Fistula lachrymalis.
	"	11.	Operation for Cataract.
	"	"	Operation for Cataract.
	"	"	Operation for Eversion of eyelid.

The fee for attendance on the joint medical and surgical practice of the hospital is reduced to ten dollars.

Beside the practice of the hospital, opportunities frequently occur of witnessing the private practice of physicians, such as the condensed population of large cities is peculiarly calculated to afford, where the poorer class is numerous, and many of them the subjects of charitable institutions.

Board in the city may always be obtained at from three to four dollars per week. The medical class of the two last years has consisted of about eighty students.

Boston, June, 1823.

NEW ENGLAND FARMER.

SATURDAY, AUGUST 9, 1823.

ACKNOWLEDGMENTS TO ADVISERS.

Some of our friends, subscribers and others, have, from time to time, favored us with goodly advice and gracious admonition, with respect to the mode of conducting our paper, which deserve respectful notice, and our tribute of thanks. We beg leave, however, to accompany our acknowledgments with the exposition of certain reasons, why we cannot always altogether comply with the wishes of many, who have been so obliging as to point out to us what they suppose to be at once the path of our duty and our high way to popularity. They say that our paper would be much more acceptable to the public in general, were it not for the dry, uninteresting, and wire-drawn articles with which column after column is crowded, to the almost total exclusion of those light and amusing matters which alone can give a charm to a periodical work. They cannot endure a "lengthy" piece, especially if it requires to be read over twice in order to be comprehended. They wish for short and pithy items, which contain a little of every thing, like the catalogue of an auctioneer.— They would have us tell them all that is deserving of the attention of the man of the world, the merchant, the mechanic, &c. as well as the complete farmer, in a few words, which shall be very appropriate, and yet so comprehensive as to embrace all that ought or can be the subject of thought, or call for the exercise of the human faculties. Scientific topics, and details of processes relating to useful but homely arts, they expect us to treat in such a manner as to arrest the attention of all classes of readers like Sir Walter's novels.

Others of our friendly dictators have taken the trouble to let us know, in substance, that if we intend to render ourselves agreeable to the more astute and sensible part of the human species, we must pay a little more homage to the ladies of Helicon. They seem to wish us to give directions for salting beef in "witty Hudibrastics," and tell the motherly house-wife how to save her bacon in galloping anapaests, like "I saw a man catch a fish with a line that was terribly tangled."

or in ambling iambs and strutting spondee like

"Stay your rude steps whose throbbing breasts incl
The legion fiends of glory or of gold."

Some well-wishers have given us both oral and written information that they are "alutely tired to death" with our endless essays on the breeds and diseases of cattle, manure, digging ditches, planting potatoes, &c. which cause our papers to be as dull as merchants' ledger, and disagreeable as a dose of ipecacuanha, before breakfast. Others complain that we are apt to be a little too learned, and soar somewhat above the comprehension of readers in general. That we sometimes make use of ear-boring and jaw-cracking words which are all Greek to farmers—that to address our disciples in an unknown tongue is harsh, orthodox, and cannot be useful.

We shall briefly take notice of some of the topics of complaint, but have not room, nor sure, nor inclination to enter at large into our own vindication. With regard to long articles we beg leave to observe that our main object in the tracts complained of, has been utility, not amusement. In giving directions relating to processes and modes of proceeding in tillage and affairs of rural economy, it is generally necessary to be minute and particular to prevent mistakes, and make our meaning perfectly understood. If we do not tell our readers all, may as well tell them nothing at all relating to these things. It will not do to set down a paragraph and leave the reader to guess at the rest. Precision is all important in matters which relate to useful arts, and it sometimes becomes necessary to relate what every body knows, who the least acquaintance with the subject, in order to introduce what is not generally known. Col. Rumford, Dr. Anderson, and many other writers on topics of rural and domestic economy, have been found fault with, and we think unjust for writing long articles and dealing too minutely in details with regard to subjects which they have treated, very much to the benefit of mankind. The sententious and aphoristical mode of writing is very improperly applied to topics where science is made the hand-maid of useful arts. Besides, we would take the liberty to tell these critical gentlemen that long articles are now-a-days, very fashionable—all the rage in Edinburgh, and quite the ton in the Quarterly Review. With regard to wit, which some of our readers acknowledge to be their chief object of pursuit, whenever they condescend to read, we must tell them that wit and humor are out of place in scientific articles. It is true, sometimes attempt something of the kind subjects of agricultural interest; but in thus doing, are actuated by the same principle which would lead us to give a piece of sugar-candy to a wayward child to induce him to learn his lesson. We yield a little to the bad taste of some

ders, and pursue a good end by means which are conscious would not bear the test of correct criticism.

As relates to being sometimes too learned for any of our readers, we shall borrow the luck of Mr. Lowell, as displayed in the last number of the Massachusetts Agricultural Journal, his shield is sufficiently capacious and impenetrable to defend us as well as the conduct of that very valuable publication. "We reproached with introducing articles, which above the capacity of common farmers. If it intended as an intimation that we devote a large proportion of this work to philosophical agriculture, we deny the fact; we also give the preference to home-bred, practical essays and experiments. But we are not only to admit that the introduction of rational scientific speculations, such as those of Kir-land Davy, is inexpedient. Massachusetts scarcely a town, which does not furnish educated men. Knowledge must be first communicated to them, and from them it will inevitably reach their less informed neighbors." In using words not of common occurrence, we have commonly introduced other words of same meaning to explain them. Thus, in using the word hydrogen, we usually accompany it with the words [inflammable air,] or if we want the word oxygen, we explain it with [air] in brackets. After all, we cannot help make our meaning always obvious to those who have no previous knowledge of our subjects of discussion. And we presume that, as we have given such words, with their explanations, several times, that our readers to whom they were new, will be so good as to select them, and not oblige us to be always repeating "line upon line." With all our care in our writings to every capacity, there be some articles which every reader can comprehend, although some other articles scientific and more practical, may be excused for his particular use. No reasoner will find fault with an entertainment use some of the dishes happen to be too highly seasoned, or otherwise not agreeable to taste, if there are other substantial and wholesome viands, which correspond with his taste.

FOREIGN.

From Cadix has been received as late as the 12th of June. On the 12th the Cortes, then sitting at Cadiz, informed the King that circumstances required a royal decree. Ferdinand replied that his consent and love for his people as a king, would not him to go; but that as an individual, he would any kind of sacrifice. The Cortes immediately chose a Regency, by whose orders the king was escorted to Cadiz, followed by the Cortes, the army, &c. On the 14th the king arrived at Cadiz, received with acclamations, and presented with keys. On the 16th the regency was dissolved, the king restored to his authority. Soon as the Cortes and the troops had left Seville, the people rose en masse, and for three days committed

great excesses on the property of the Constitutionalists, who had left the place. They were, however, dispersed by Gen. Lopez Bances, who levied a contribution of \$50,000 on the clergy, by way of atonement for the excesses of the populace. The French had not reached Seville at the date of the last accounts. The Cortes were in session at Cadiz, determined to defend that place to the last extremity.

On the 13th, at Cadiz, the Minister of War *ad interim*, Don Stanislaus Vaneche Salvador, was found dead, with his throat cut with a razor. A note written with his own hand was found in a window of his chamber, in which he stated his intention of destroying himself; observing that life was becoming every day more insupportable to him—that his conscience did not accuse him of ever having committed crime or offence, and that he mentioned this in order that no other person may be in any manner accused or implicated.

At the last session of the British Society for the Encouragement of Arts, Manufactures and Commerce, a premium of thirty guineas was granted to Messrs. Cowley & Staines, of Winslow, Berks, for preparing one hundred and forty-three pounds of Opium, from poppies raised in England.

There are now nineteen counties in England, into which the tread mill has been introduced; and it has uniformly followed, that those persons who have been subject to the discipline of that machine, have, at the expiration of the terms of their imprisonment, shown a strong disposition to forsake their former dissolute habits, and have returned into society with improved ideas of rectitude and morality.—*Poismouth Journal*.

The daughter of a Greek, called *Spartan*, has traversed the islands in the garb of a warrior, and called upon the young men to enlist under the banners of their country. She recruited, by her activity and enthusiasm, sixteen companies of 50 men each, placed herself at the head, and proceeded with them to *Napoli di Romania*.

DOMESTIC.

Michigan.—A trading and hunting party, consisting of about 75 Americans, commanded by Gen. Ashley, left St. Louis last spring for the Rocky Mountains. On the 2d of June, 2 or 3 hundred miles above the Council Bluffs, they were attacked by the Recaras Indians, who killed 14 of the American party, and wounded 9. Gen. Ashley then took post, with one boat and thirty men, a few miles below where the attack was made, and sent his wounded and disabled men back to the Council Bluffs. Col. Leavenworth, by order of Gen. Atkinson, marched from the Council Bluffs on the 22d of June, with a body of troops and friendly Indians, to punish the Recaras, who were reported to have taken post and fortified themselves.

Three daughters of Mr. Marcus Robbins, of Hampton, Vt. lately spun, in one day, 345 knots of good woollen yarn, or 115 knots each.

Two young cattle lately died in Pawlet, Vt. in consequence of eating dried black cherry leaves. The leaves operated as a very powerful poison.

American Duck.—We have just examined several specimens of this article from the manufactory of Mr. George Johnson, Salem, Mass. This Duck doubtless possesses, in every respect, the superiority over any of foreign manufacture—being made of pure flax, every thread, both warp and filling *doubled and twisted*, without the addition of any glutinous or acrid substance which might expose it to mildew. Of its strength and durability the highest commendation is furnished by the government of the United States, who have contracted for its exclusive use in the navy—after testing its utility by satisfactory experiment. We confidently recommend it to the notice of merchants and ship owners in this place.—*Nantucket Enquirer*.

A young man of Mercer, (Pa.) having been to grind a scythe, on his return, being on horseback, and carrying the scythe crossways before him, the horse started, and the heel of the scythe caught a bush, which drew it across the young man and cut him in so shocking a manner as to cause instant death.

How to cure a Wen.—A gentleman of Baltimore, who for 11 or 16 years was plagued with a wen on his head, for which he could find no cure, happened a short time ago in a frolic with a *young Irishman* to receive a severe blow directly upon the excrescence, which entirely removed it. The operator is very willing to try his skill in any other cases that may offer.

Tow Cloth.—There is no article of domestic manufacture so much wanted as stout Tow Cloth. The filling and the warp should be of equal firmness and size, and full forty inches wide, as this article is principally wanted for bailing up Domestic Cotton Goods. It need not be very fine, but it should be very stout and firm. Our New Hampshire friends are particularly requested to attend to these remarks, as the Tow Cloth which comes from that State is so thin and *slazy* that no manufacturer of Cotton Goods will buy it.—*Continued*.

A Great Shark.—A Shark, when alive, measuring from 12 to 13 feet in length, and weighing about 1000 pounds, was presented to the Alexandria Museum, by Capt. Joseph Marbury, of that town. This monster of the deep was taken by the donor, in the Atlantic Ocean, and is supposed to be the largest ever preserved for any museum in the United States.

Several buildings were injured by lightning during the storm last Monday evening.

FALLS OF THE MOHAWK.

The following lines, written by the celebrated Thomas Moore, at the Cohoes, or Falls of the Mohawk river, contain many beautiful images, derived from river scenery. The language and thoughts are characterized by that liquidity and exactness for which all Moore's poems are distinguished. The country in the immediate vicinity of the Cohoes has a peculiarly wild and dreary character; and when the sun is in the right position, a fine rainbow is painted on the spray, which is continually rising from below the falls. These circumstances explain the allusions in the verses. We wish that all Moore's poetry was as free from an immoral tendency.

From rise of morn till set of sun,
I've seen the mighty Mohawk run;
And, as I mark the woods of pine
Along his mirror darkly shine,
Like tall and gloomy forms that pass
Before the wizards midnight glass;
And, as I viewed the hurrying pace
With which he ran his turbid race;
Rushing, alike, untir'd and wild,
Thro' shades that frown'd and flowers that smil'd,
Flying by every green recess
That wou'd him to its calm caress;
Yet, something turning with the wind,
As if to leave one look behind:
Oh! I have thought—and thinking sigh'd—
How like to thee, thou restless tide!
May be the lot—the life of him
Who roams along thy water's brim;
Through what alternate shades of woe,
And flow'rs of joy, my path may go;
How many an humble, wild retreat
May rise to court my weary feet,
While still pursuing—still unblest,
I wander on nor dare to rest;
But urgent as the doom that calls
Thy water to its destin'd falls,
I see the world's bewildering force
Hurry my heart's devoted course
From lapse to lapse, till life be done,
And the lost current cease to run.

Oh! may my falls be bright as thine:
May Heaven's forgiving rainbow shine
Upon the mist that circles me,
As soft as now it hangs o'er thee!

Singular recovery of a Female unjustly executed!

The following account of the case of a poor girl, who was unjustly executed in 1766, is given by a celebrated French author, as an instance of the injustice which was often committed by the equivocal mode of trial used in France.

"About seventeen years since, a young peasant girl, possessed of a very agreeable figure, was placed at Paris in the service of a man depraved by all the vices consequent on the corruption of great cities. Smitten with her charms, he tried every method to seduce her; but she was virtuous, and resisted. The prudence of this girl only irritated the passion of her master, who, not being able to make her submit to his desires, determined on the most black and horrible revenge. He secretly conveyed into her box many things belonging to him, marked with his name. He then exclaimed that he was robbed, called in a commissaire (a ministerial officer of justice) and made his deposition. The girl's box was searched, and the things were discovered. The unhappy servant was imprisoned. She defended herself

only by her tears; she had no evidence to prove that she did not put the property in her box; and her only answer to the interrogatories was, that she was innocent. The judges had no suspicion of the depravity of the accuser, whose station was respectable, and they administered the law in all its rigor; a rigor undoubtedly excessive, which ought to disappear from our code to give place to a simple but certain penalty which leave fewer crimes unpunished. The innocent girl was condemned to be hanged. The dreadful office was ineffectually performed, as it was the first attempt of the son of the great executioner. A surgeon had purchased the body for dissection, and it was conveyed to his house. On that evening, being about to open her head, he perceived a gentle warmth about the body. The dissecting knife fell from his hand, and he placed in his bed her whom he was about to dissect. His efforts to restore her to life were effectual; and at the same time he sent for a priest, on whose discretion and experience he could depend, in order to consult with him on this strange event, as well as to have him for a witness to his conduct. The moment the unfortunate girl opened her eyes, she believed herself in the other world, and perceiving the figure of the priest, who had a marked and majestic countenance (for I know him, and it is from him that I have this fact,) she joined her hands tremblingly, and exclaimed 'Eternal Father, you know my innocence—have pity on me!' In this manner she continued to invoke the Ecclesiastic, believing, in her simplicity, that she beheld her God. They were long in persuading her that she was not dead—so much had the idea of the punishment and of death possessed her imagination. Nothing could be more touching and more expressive than the cry of an innocent being, who thus approached toward him whom she regarded as her Supreme Judge; and, independently of her affecting beauty, this single spectacle was sufficient to create the most lively interest in the breast of an observing and sensible man. What a scene for a painter! What a moral for a philosopher! What a lesson for a legislator!

The servant having returned to life, recognised a man in him whom she had adored, and who directed her prayers towards the only adorable Being, quitted the house of the surgeon, who was doubly uneasy on her account and his own. She retired to hide herself in a distant village, fearing to meet the Judges, or the Officers, who, with the dreadful tree, incessantly haunted her imagination. The villainous accuser remained unpunished, because his crime, though manifested to the eyes of two individual witnesses, was not so clear to the eyes of the Magistrates and of the laws. The people subsequently became acquainted with the resurrection of this girl, and loaded with reproaches the execrable author of her misery; but, in this immense city, his offence was soon forgotten, and the monster perhaps still breathes;—at least, he has not publicly suffered the punishment which he deserves.

Industry.—It is an immutable decree, that the oil of gladness shall brighten the face of industry alone. For how much virtue and happiness are not men indebted to that constitution of things, which imposes upon them an obligation to act and to refrain.

From the Amherst (N. H.) Cabinet of August 2

The following remarkable event occurred Bedford, on Thursday of last week. A young girl, of about 14 years of age, was assisting the taking away of grain in the sheaf upon scaffold on the great beams of the barn, when she accidentally fell from the scaffold, a descent of 7 or 8 feet, on to a stake of the cart which had just been unloaded. The stake entered her body, passed up the rectum, and came out the left side near the breast, so that she completely transpired upon it. The stake was so attached to others by the rive of the cart that it could not be removed until the others were broken off, when it was forced from socket in the cart, and the girl carried out the barn before it could be extricated from it. During all which time the girl held on by the top of the stake which had passed through her side sufficient for her to take hold of with her hands, six or seven inches at least. A most distressing situation cannot easily be imagined. The length of the stake which passed into her body measured full 27 inches; and in circumference was 5 inches at the largest, and at least inches in the smallest part of it. And what is equally remarkable, the girl is doing very well and likely speedily to recover—and has apparently undergone less suffering than could possibly be conceived of in such a case.

From the Providence Gazette.

A remarkable instance of malice in a horse owned by a person near this town, we have heard related on good authority. A person a few years since was in the habit, whenever wished to catch his horse, to take a quart of corn in a measure, when, calling to him, the horse would come up and eat the corn with the bridle was put over his head. But the owner having deceived the animal several times by calling him when he had no corn in the measure, the horse at length began to suspect his design—and coming up one day usual, on being called, looked into the measure, and seeing it empty, turned round, reared his hind legs, and killed his owner on the spot.

Webb, the celebrated walker, who was remarkable for vigor both of body and mind drank nothing but water. He was one day commending his regimen to a friend who had wine, and urged him with great earnestness to quit a course of luxury by which his health and his intellect would be equally destroyed. The gentleman appeared to be convinced, and told him that he would conform to his course, though he could not change his course of life at once, but would leave off strong liquors by degrees. "By degrees!" exclaims Webb, "if I should unhappily fall into the fire, would you caution your servants to pull you out by degrees?"

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrearages are paid.

Agents who procure seven subscribers, and are responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

[BY THE EDITOR.]

DRAINING LAND.—Concluded from p. 10.

In our former observations on this subject we treated principally of *open drains*, and shall now make some remarks on *covered or hollow drains*, their different sorts, modes of construction, &c., and conclude with directions respecting the abutting and cultivating of lands, which have been drained.

Although covered drains are not so frequently called for in this country as in the old and populous parts of Europe, still there are situations on this side of the Atlantic in which they will be found convenient if not indispensable. We find nothing on the subject of their construction and advantages more concise, perspicuous and pertinent, than the following from *Encyclopædia's New England Farmer*.

"To make a hollow drain, dig a channel between thirty and thirty-six inches wide at the top, and six inches, or the breadth of a spade, the bottom, and three feet deep, giving it a descent enough to make the water run easily. Fill it half full or more with small stones, thrown in at random, and cover them with a layer of straw, leaves, or the small branches of trees with the leaves on them; then fill it up to a level with the surface with the earth which is thrown out. Such a drain will not often choke or fill up, or need repairing. If the descent should be but just so much to make the water run slowly, there may be no danger of its choking up and ceasing to run at all. But this danger will be greater or less according to the difference of soils. There will be no danger of it in a soil which does not easily dissolve in water.

If stones be scarce, long faggots or fascines (bundles of wood) laid in the trench, will answer well, so long as they last, and being secluded from the air, will not soon rot. Some say they are known them to answer well for forty years, but this must only be in places where they are always kept wet. In situations exposed to wet and dryness, they perish in five or six years.

If a plain piece of ground be too wet to be fitted for tillage by ridge ploughing, it should be made drier by hollow drains. If no lower place be adjoining where the drains may have outlets, holes should be dug in some of the best parts of the plain, to examine what is under the soil. It is likely that a mass of clay, or of some other earth not easily penetrated by water, is the real cause of wetness of the soil. If you find it so, then dig through the stratum and below it till you come to loose gravel, sand, or something that easily imbibes water: fill up the hole with stones and direct your hollow drains to it. It will serve for a perpetual outlet, and conduce to the drying of the soil.

The peculiar advantages of hollow drains are that they will not need repairing, as they do not fill up; that no soil is wasted, or rendered useless by them; that a plough may pass over them to as great a depth as is necessary

in any kind of tillage; and carts and other carriages are not obstructed or incommoded by them. So that these drains may pass across roads without detriment when the descent requires it. It is often found necessary to hollow drain roads to lay them dry, and found to be of great advantage."

Drains which are intended to be ultimately covered, may be dug with a plough, an ox-shovel, or scraper, &c. (as directed in our last No. page 9) and it will sometimes be found expedient to begin with those implements, and finish with the spade. Care should be taken in making drains of this kind that the depth be such as to allow a proper quantity of earth above the drain, that the materials in the ditch and the substances which cover it may not be injured by the pressure of the horses or cattle in ploughing, &c.

A variety of materials besides stones may be used for filling covered drains. We have mentioned billets of wood, and would now add that thorns bound in bunches, green bushes, either taken in the season when they are not in the leaf, or with the leaves stripped off, green willows bound in bundles, or laid as compact as possible, and even straw, either twisted into ropes as thick as a man's leg, or thrown in loose, may answer in lieu of better materials. The durability of the substances which are used for partly filling covered drains, is not of so great consequence in clayey soils as the probability of having a sufficient opening for the water to flow through; for clay generally forms an arch over such substances, which supports the superincumbent soil, and leaves a clear passage for the water below when they have decayed. Care should be used in covering the materials which have lodged in the water-course of the drain, that no earth be allowed to make its way, so as to obstruct the water. The loose straw, leaves, branches of trees, dressings of flax, &c. which intervene between the earth or soil which lies on the top of the drain and the materials which lie in the water-course, should be placed with a careful hand before the drains are filled up, and the drains should be filled up as soon as possible after they are ready for that operation.

Covered drains are likewise often made hollow, and are sometimes arched; at others regularly built with perpendicular sides, and covered with flat stones, but are too well known to need a more particular description. There is a kind of covered drain, which has been adopted in English husbandry, and may be thus described: A trench is dug of a proper and convenient width, not less than three feet deep.—When it is dug down to within four or five inches of the whole depth designed, shoulders are left on each side, and a kind of groove or channel is cut for the water-course at the bottom of the drain, or trench, below those shoulders. On the shoulders sods or turfs are laid in such a manner as to cover the grooves or water-course which lies below, and at the bottom of the trench. The grass side of the turf is placed down, and the earth is thrown over the whole. This kind is made at a small ex-

pense, and may continue hollow and discharge well for many years. It may be called the *turf covered drain*, and is not only a very cheap mode of constructing drains, but probably new in this country.

Another mode of making turf covered drains, still more simple, may be thus described: Turn up a deep furrow with a strong plough, clear the sod from the earth thus turned up, reduce it to about three inches in thickness, and then place it in the furrow from whence it was taken. The grassy side being placed uppermost there is a hollow beneath, sufficient to discharge a considerable quantity of surface-water, which readily sinks into it. This mode of draining is used in the sheep farms of the Cheviot hills in England, and is recommended by Sir John Sinclair. It would not answer, however, in lands exposed to the tread of heavy cattle, as they would be apt to push their feet through a covering of turf of no more than three or four inches. Perhaps however in a few years, the verdure would thicken and the sward strengthen over drains of this kind, so that there would be nothing to apprehend from pasturing the largest animals in fields drained by this method. It is almost too obvious to require any remark that the water obtained by draining may be employed to turn mills, or to irrigate lands, &c.

We have now completed our observations on the different kinds of drains, and the different modes of making them, and shall dismiss the subject with some remarks on the cultivation of drained land.

It is not necessary to dwell on the fertility of most drained lands. It is well known that swamps, marshes, and other low lands are commonly places of deposit for the lighter and more fertile parts of the soil washed from the neighboring hills. Many marshes are in fact intervalle land, naturally too wet for profitable cultivation. Wet lands, which receive the wash of higher grounds of a tolerable quality, may be expected to be fruitful and worth going to some considerable expense for draining. A bog however on the top of a hill not overlooked by high ground, we should suspect of barrenness, and would not be at great expense for draining it without examining and analyzing the soil in various parts, and becoming satisfied of its fertility. But a drained marsh, which by the help of a sluice and gate, can be flooded at the option of the owner, with water which has washed the neighboring uplands, may be considered as inexhaustible, and perhaps had better be appropriated to the raising of hemp. That plant requires such strong land to produce it that it would need all our manure to raise it in great quantities on common upland. If the land is rich, not very dry, or water can be set back in the ditches in a dry time to within three or four feet of the surface, it will be quite an object to introduce Fowl Meadow (*Agrostis stricta*.) The value of this grass is too well known to need eulogy. Once introduced in land to which it is adapted, it will remain good for a great length of time, and generally yields from three to four tons to an acre of the best of hay. And this great and valuable product is yielded without

manure. It is said, however, to be difficult to cause the seed to grow unless on a surface which has been burned or ploughed over.

It is frequently best to let drained lands lie over one summer to ferment and rot, before any attempt to cultivate them. Flooding them completely in the winter, and drawing the water quite off rather late in the spring, will likewise greatly expedite the business of rotting the sod.

Burning the moss from drained land is a practice strongly recommended by some writers, and as strongly reprobated by others. Mr. Elliot says, "it is common in swamps to find the moss two or three feet deep—but when the water is drawn off by ditches, the moss will grow so dry that in a hot summer season it will burn quite down to the ground. To burn this or any other trash that you would consume upon the ground, set fire to it when the weather is quite clear, the sun hot, and a strong southerly wind blows, which makes fire rage more fiercely and do much more execution than a northerly or westerly wind. In a northerly wind the air is thin and light, so that the fire is not strongly compressed: the most heavy south wind prevents the dissipation of the fire, and renders it more compact. Thus we see a smith swab and wet his coals, by which means the heat is greatly increased. Whether this reasoning be just or not, the fact is certain, and this is the chief concern of the farmer."

Burning the moss and other vegetable substances of a swamp or bog may sometimes be expedient, but it causes a great waste of matter which is capable of becoming good manure or food for plants. If it is possible to subdue the tract by other means, burning should be avoided. If a farmer has a small piece of marshy land, consisting of mud, peat or moss, he may as well in many instances transport, from time to time, these substances into his barn yard and hog pen, to receive the liquid manure of his cattle, swine, &c. and to form composts with dung, for which they afford excellent materials. And while he thus digs out a slough, bog or morass, he may perhaps be forming an useful water pond for his cattle. A spot of this kind, which has for ages received the wash of adjacent land, and formed a lodgment for fallen leaves, &c. may prove a mine of manure, very valuable to the farmer who knows how to appreciate its benefits. Scooping out a part of such a slough, will, perhaps, so far drain the rest that foul meadow grass, or some other valuable product, may be made to grow on it.—Thus the cultivator may at the same time procure a rich material for compost, form a pond for watering his cattle, and drain the ground in its vicinity.

We have now completed, for the present, our remarks on this important branch of husbandry. We hope we have suggested some useful ideas which were not before familiar to every farmer who may have occasion to drain and cultivate the kind of land of which we have treated.—The modes of making Turf-covered Drains in particular, were new to us, till we began the investigations preparatory to penning this article. We hope that in this part of the essay, at least, we may have communicated some ideas which may prove new as well as useful to some of our readers. To those who complain that our essays want novelty, we would reply, that

under the head "Remembrancer," we aspire to nothing more than to put the rural economist in mind of what it is presumed he knew before, but which, in the hurry of business, may have escaped his attention. We are perfectly sensible that practical farmers might suggest many important amendments and improvements to our observations on this as well as other branches of the important art to which our paper is devoted; and we hope our doing what we can may induce others more able to perform more than we can, by way of adding to the public stock of agricultural knowledge.

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY. FOR THE NEW ENGLAND FARMER.

ON FATTENING FOWLS, TURKIES, &c.

R. Weston, Esq. an English writer of reputation in a work entitled *Tracts on Practical Agriculture and Gardening* has the following observations on this subject, which may be worth the attention of those who wish to find an early, and of course a profitable market for poultry.

"Boil some rice in water, gently, till it be plumped up and very tender; add about two ounces of very brown sugar to every pound of rice, just before it be boiled enough; let the fowls be fed with it three times every day; in ten or twelve days they will be fat, but if they were in good condition when put up to fatten, they will be ready in seven or eight days; they must, by no means, have any water given them: in summer, too much rice must not be boiled together, because of its soon turning sour; nor is milk so good for that reason, as water only; besides, the milk is very liable to make the rice burn to the pot.

"Frequently oil-rice is to be bought very cheap of the grocers, in the city. The rice causes the flesh to be remarkably white, and to have a fine delicate flavor."

The Complete Farmer observes, that "if fowls are fed with buck wheat, or with hemp seed, it is said they will lay more eggs than ordinary; and buck wheat, either whole or ground, made into a paste, which is the best way, is a grain that will fatten fowls or hogs very speedily; but the common food used is barley meal, with milk or water; but wheat flour moistened is best."

Indian corn boiled or made into paste or hasty pudding, would, no doubt, answer as good a purpose as rice or any other food; but, we believe the addition of something sweet, such as molasses, or maple sugar, or probably boiling with the grain a portion of corn-stalks, red beets, ripe pumpkins or squashes, or something which would sweeten the food, might quicken the process of fattening. Boiled or steamed potatoes are said to make an excellent food for poultry.

For fattening ducks and geese, Mr. Weston gives the following directions:—Mix some ground malt with warm water, or rather skimmed milk, and feed your geese and ducks with it three times a day, at the same time let them have plenty of clean water, as it causes them to drink freely; two gallons of malt are in general more than enough for a young goose, and less than one is sufficient for a duck; it has an amazing quality in fattening them when young, and causes the flesh to be very delicate; when

they are old they readily fatten with almost a food; but for the flavor it gives the flesh should always prefer malt before any thing else. Before they have been put up to fatten, I have given both ducks and geese plenty of lettuce which they are exceedingly fond of; they are very cheap food for them, as they need but have but little corn."

In speaking of fattening turkeys, the same author has the following observations:

"The method here proposed, may appear some persons very odd, and scarcely to be credited; but having frequently practised it, I can assert the truth of it.

"Pitch on such turkeys as are in tolerable good condition; to prepare them for being killed about the sixteenth day, give them every morning about the time when they have just eaten their corn, a walnut, the bitter husk which only shall have been first taken off, (the shell must not be cracked, lest the rough edges tear their throats); pick out the walnut according to the size of the turkey; on the second morning give them two; on the third three; on the fourth, four; on the fifth, five; on the sixth, six; on the seventh, seven; and continue to give them seven for two days, then decrease the quantity, and give them the ninth day only six; on the tenth, five; the eleventh, four; on the twelfth, three; the thirteenth, two; on the fourteenth, one; then put them up, and after making them fast for one day, kill them.

"They are to continue in the yard, with all other fowls, all the time; but about the fourth or fifth day they will have little relish for a corn, but rather choose to retire into some warm corner, and there set down; therefore there should be a shed for that purpose open to the south.

"This method takes exactly fifty-six walnuts for each turkey, and I have scarce ever found it necessary to have it altered; but their being continued to have seven walnuts for two, three or four days, makes no great difference, and a little experience will soon teach each part of the practice. The reason for giving them more at first, is to use the stomach of the fowl to them by degrees. If the walnut be rubbed with a piece of butter or hog's lard they slip down the easier.

"The time I have had turkeys fed in this manner, has been from October to January; they have always succeeded very well; the effect the walnuts caused on the flesh was to make it of a fine silver white color, particularly the fat, and of a remarkably delicate flavor quite superior to its usual taste when fed with any other kind of food.

"Were the attempt made to fatten fowls with walnuts, the shells should be cracked, and the kernels given them. The fattening corn should always be set in a very airy dry place and cleaned every day, else the smell of the dung will take away their appetite; whenever that should be the case, they should be taken out of their coops, and suffered to run about the poultry yard, to recover their health before they are put up again. If the coops be kept in a dark place, or covered with mats or cloths, exclude the light, the fowls will the sooner fatten, but care must be taken that there be free circulation of air."

We do not pretend to say that it will be worth

while for our farmers in general, amidst the multiplicity of more important concerns, to be at the pains to fatten turkeys on walnuts.—At there are some persons who attend to rural economy merely for amusement, who may as well turn their pursuits into that channel as any other still less profitable and not so amusing. Besides, something may be learned from such processes, even by those who do not adopt them. Mr. Weston's beginning to feed his turkeys with a walnut each the first morning, two the second, and so on, gradually increasing to a certain quantity, and as gradually decreasing after they had received a full supply, may teach us not to fatten or surfeit an animal when first put up to fatten. In this way we may bring on a fever, otherwise injure the health of the poor thing which undergoes such operations. Swine, in particular, we believe are often injured by a sudden change from a very meagre to a very rich and plentiful diet; and when they have been partly fattened they require a less quantity of food, and food is perhaps more profitably stowed on the latter stage of fattening; or as better expressed in a late work by Mr. Cobb, called *Cottage Economy*:—"When you get to fat, do it by degrees, especially in the case of hogs under a year old. If you feed *high* at once, the hog is apt to *surfeit*, and then a great loss of food takes place. Make him *quite* by all means. The last bushel, even if he has his ears, is the most profitable." The reasoning, if not carried to extremes (for hogs may be made too fat either for pleasure or profit) may be applied to turkeys and other fowls.

We shall conclude our observations on turkeys, by some further quotations from Mr. Cobb's work above mentioned.

The great enemy to young turkeys (for old ones are hardy enough) is the wet. In America where there is always "a wet spell" in November, the farmers' wives take care never to let a brood come out, until that spell is passed.

In England, where the wet spells come at hazard, the first thing is to take care that young turkeys never go out, on any account, in dry weather, till the dew is quite off the ground; and this should be adhered to till they are the size of an old partridge, and have their backs well covered with feathers. And, in wet weather, they should be kept under cover all day long.

As to the feeding them, when young, variety of things are recommended. Hard eggs, mixed fine with crumbs of bread, and a great variety of other things; but, that which I have seen, and always with success, and for all sorts of young poultry, is, milk *turned into curds*. This is the food for young poultry of all sorts. It should be made *fresh every day*; and, if it is done, and the young turkeys kept warm, especially from wet, not one out of a score die. When they get to be strong, they may have meal and grain, but still they always like the curds.

When they get their *head feathers* they are strong enough; and what they then want, is, to grow about. It is best to breed them from a common hen; because she does not run to fatten a hen-turkey; and, it is a very curious

fact, that "wet spell" as frequently visits us in May as at least in the Northern States.

thing, that the turkeys, bred up by a hen of the common fowl, do not themselves *run much when they get old*; and for this reason, when they buy turkeys for stock, in America (where there are such large woods and where the distant rambling of turkeys is inconvenient,) they always buy such as have been bred under hens of the common fowl; than which a more complete proof of the great powers of habit is, perhaps, not to be found. And, ought not this to be a lesson to fathers and mothers of families?—Ought not they to consider, that the habits which they give their children, are to stick by those children during their whole lives?

"The hen should be fed exceedingly well too, while she is sitting and after she has hatched; for, though she does not give milk, she gives heat; and, let it be observed, that, as no man ever yet saw healthy pigs with a poor sow; so no man ever saw healthy chickens with a poor hen. This is a matter much too little thought of in the rearing of poultry; but it is a matter of the greatest consequence. Never let a poor hen sit; feed the hen well while she is sitting; and feed her most abundantly when she has young ones; for then her labour is very great; she is making exertions of some sort or other during the whole twenty-four hours; she has no rest; is constantly doing something or other to provide food or safety for her young ones.

"As to fattening turkeys, the best way is, never to let them be poor. *Cramming* is a nasty thing, and quite unnecessary. Barley-meal, mixed with skim-milk, given to them, fresh and fresh, will make them fat in a short time, either in a coop, in a house, or running about. Boiled carrots and Swedish turnips will help, and it is a change of sweet food. In France they sometimes *pick turkeys alive* to make them tender; of which I shall only say, that the man that can do this, or order it to be done, ought to be skinned alive himself."

From the American Farmer.

SALIVATION OF HORSES.

Moorfield, (Va.) July 1, 1823.

MR. SKINNER—Some of your correspondents have expressed their opinions of the cause of the salivation of stock during the summer; as it affects horses in particular. As it seems to be a question of some considerable difficulty, and as there are a variety of conflicting sentiments upon the subject, I will submit to you my opinion also; having repeatedly observed its effects, and as often endeavoured to ascertain the cause.

The supposition that appears to me most probable, is, that it is produced by the mould on the grass, to which it is extremely subject. An attentive observer may, about sunrise, frequently perceive streaks of blue mould on the grass, and by reviewing it more closely with a magnifying glass, he can distinguish two complete rows of mushrooms, or fungi, one on each edge of the spear grass. As the sun rises over the horizon, he discovers these to ripen, open at the extremity, and expose a small cluster of four or five seeds, after which they soon disappear. About this period the blade is destroyed, and it becomes visible by the grass becoming dry—the mould is not so easily discovered in clover as in spear grass; the former resembling it in color more than the latter. I

have for some time been impressed with the belief, that the salivation of stock is caused by their feeding upon this mould, or rather the grass, after the fungus had matured; and I have been almost confirmed in my opinion by the result of a practice we have pursued of confining our labouring horses on newly mowed meadows, from which the old grass is entirely removed. By adopting the above course, the salivation is effectually prevented, or at least considerably abated. In addition to the above practical proof, I have observed that our brood mares and younger horses, which are generally pastured upon our most barren lands, where the grass is not so luxuriant in its growth as to produce the mould, are scarcely ever affected with the above mentioned malady.

Respectfully yours,

ABEL SEYMOUR.

☞ This subject really demands the fullest investigation. Is it not an evil of comparatively modern date? Is it not aggravated by wet weather, when vegetation is more luxuriant? Why is it produced by second crop clover hay, and not by first? Do not neat cattle and other ruminating animals suffer with it, although the effect is not exhibited by salivation, as in the case of horses? We ask this question because the editor is now in his native Calvert County, where he has been struck with the extraordinary low condition of neat cattle, both cows and oxen. He never saw weather more favorable, or grass more abundant in the pastures, and yet the cattle as well as horses, are extremely reduced in flesh, while the latter only are slabbering at a degree that one would suppose would exhaust them unto death.—*Ed. Amer. Farmer.*

A burlesque upon Duelling was practised at Chelmsford one evening last week; the parties were a Master Carpenter and a learned gentleman of the *Comb*, who has recently removed a Latin inscription from over his door, which conveyed a meaning too much the reverse of what he practises, "Always at home." A dispute arose, we are informed, between these two heroes, "which was the best beer—that which had undergone fermentation, or that which had not." The frequent tasting of both got the better of the senses of the disputants, and from high words they proceeded to practise high notions. Nothing short of pistols would suffice; they were procured, but the *Knight of the Comb* preferring powder to lead, so managed to bribe the seconds, that the deadly part of the charge was not introduced; whilst the *Knight of the Chisel* was not in the secret. To carry on the joke, the former feigned to lament (what both may one day regret in earnest) that he had not taken leave of his wife and family, and urged the necessity of a few minutes for purposes, unfortunately directly opposite to his intentions, after which the combatants took their ground in the room. The Carpenter having the privilege of firing first, his opponent fell, when at the instant, the better to keep up the farce, the lights were put out, the Carpenter received a cooling glass of water in his face, and both were left in the dark to reflect upon their folly.

The crops in Virginia, North Carolina, and the middle and eastern states are said to be unusually good.

FOR THE NEW ENGLAND FARMER.

Silver Lake, Susquehanna Co. Pa.
Aug. 4, 1823.

DEAR SIR,

I have received and read the first volume of the N. E. Farmer. If the work shall be continued with the spirit and intelligence with which it has hitherto been conducted, it will be of great service to the farmers of the U. States. It is very gratifying to see that agriculture is becoming a fashionable pursuit among those who desire to mingle pleasure with profit—the *ju-cunda et idonea*; and that it is taking the rank in our country, to which it is entitled by its great national importance. Agricultural papers are very useful in aiding this, by the detail of well authenticated facts, to prove the best mode of culture; by the publication of scientific essays on the subject; and by making agricultural men acquainted with each other, urging them to perseverance in their labors, and shewing them the interest which is taken in the objects of their pursuit.

I perceive by your poet's corner, that you have not abandoned the muses.

Quo semel est imbuta recens, servabit odorem
Testa diu.

A taste which nature has planted deeply, is not easily lost. Indeed, when we met at our literary friend D's, many years ago, if I had been told that you would publish a work on Agriculture, I should have expected it to be purely Virgilian, that you would begin with *Quid faciat letas segetes*,* and that all your crops would be measured by dactyls and spondees.

It would give me much pleasure to contribute to your work, as you desire; but your pages are already well filled with original and selected matter; and you have among your correspondents many who are much better practical farmers than I am; and experiments, and their results, are what farmers seek. I might, however, suggest to them, as a very important part of their communications, the necessity of noticing the *kind of soil* upon which their experiments are made. A scientific farmer can tell, from a specimen of earth exhibited to view in his study, what crops would grow best on it, as easily as a geologist can say among what particular kinds of rocks certain metals are to be found; and a farmer without science, may easily learn to distinguish the different kinds of soils, which are designated by the relative proportions of their component parts. To plant in clay that which grows best in sand, or vice versa, is an useless expenditure of labor; and a little attention to this subject, would frequently prevent the loss of both time and money.

In No. 17 you have quoted from Judge Cooper's notes to Willich's Domestic Encyclopedia, that "there are many districts of Pennsylvania, perhaps the best pasture land in it, that do not contain a particle of lime stone. Such for instance as a great part of Luzerne, and the Beech Country, comprehended between the north east branch of the Susquehanna, and the south line of the state of New York and the Delaware river. There is no finer grass country."

The greater part of the "Beech Country" mentioned by the judge, constitutes now the county of Susquehanna, and deserves the char-

acter which he gives of it as a grass country. It receives its name from the prevailing timber; but that is considerably mingled with hemlock and sugar maple, and in less abundance with birch, ash, chestnut and cherry. The inhabitants are principally from the eastern states. The settlement has been very rapid. Fifteen years ago it was a wilderness. It is now tolerably well settled; but land is still cheap; that which is unimproved may be had from three to six dollars, and farms are sold at from eight to twelve dollars per acre. The country is remarkably healthy and well watered. The soil is a sandy loam generally about eighteen inches deep, incumbent on a subsoil which is formed of *extremely fine siliceous sand and alumine*, very compact, and here called "hardpan;" a name, I believe, of N. England origin, for I do not recollect to have heard it elsewhere. This kind of subsoil is found in Pennsylvania wherever the beech, maple and hemlock are the prevailing kinds of timber, and its power of retaining water, is a great cause of the kinds of timber which grow on it, as well as of its fertility as a grass country.

Sir John Sinclair prefers a porous subsoil, and considers a retentive one as injurious to the crops. This opinion is contradicted by the American Editor of the Code of Agriculture, who says that the finest grass lands in New England have only a thin coat of loam on a stiff clay; and that, on such soils, there is no loss of moisture by filtration. Perhaps both parties may be right in their respective situations; for in many parts of England and Scotland, for which Sir John's work is particularly calculated, the farmer has to guard against excess of moisture, while in our country we suffer from the want of it. Col. Powell mentions (see No. 35 of the N. E. Farmer,) that "the English farmer wisely contends with the evils produced by too much rain, while the American husbandman should as anxiously guard against his most formidable enemy, drought." I believe this has not been sufficiently attended to by American farmers.

In our climate, a soil which is best adapted to absorb moisture, when resting on subsoil which prevents its filtration and waste, is the one best calculated for grass, oats, and broad leaved crops. It has been observed by one of the best informed English writers on this subject, that "in wet climates crops exhaust the soil less than in dry ones;" and that "the same quality of soil is more productive in a moist than in a dry climate." A difference equal to that between a moist and a dry climate, is made by the difference between a retentive and a porous subsoil; especially if he who possesses the former, shall, according to the advice of Col. Powell, in the tillage of his land, endeavor to protect the soil from the great exhalations occasioned by the sun of our climate.

As it would be useful to agriculturists to obtain analyses of different soils, which have been found to be peculiarly adapted to raising of particular kinds of vegetables, I send you an analysis of the soil and subsoil of our beech lands; and perhaps you may draw others from some of your correspondents. It is to be observed, that the soil and hardpan submitted to the tests were in the state of nature; that is, taken from a part of the land lately cleared of its timber, which had neither been ploughed nor manured. The soil was taken a foot below the surface.

	Soil or Vegetable mould.	Hardpan
Silica,	67.8,	73.6
Alumina,	7.3,	12.2
Carbonate of lime,	1,	2,
Oxide of iron,	7,	7.4
Vegetable and animal matter lost by	8.9,	4.2
Calcination,		
Magnesia,	6.2,	
	98.7,	99.4
Loss,	1.3,	.6
	100,	100

It will be seen by the above that the soil is not quite, as judge Cooper says, "without a particle of limestone;" but that it contains a very small portion of lime. The hardpan appears to contain twice the quantity which is found in the soil; and as I have seen carbonate of lime throw out of a well in this neighborhood, it is probable that there is limestone to be found deep in the ground. But this does not affect the vegetation.

It has been suggested by a friend, and I think with much plausibility, judging from the similarity of the constitutions of the soil and subsoil that the former has been made from the latter by the action of the frost, and extends to the depth which the frost penetrates in severe winters. This opinion is strengthened by the custom of masons in laying the foundation of buildings here, who never think it necessary to go deeper than to the hardpan. When the latter has been turned up, and exposed to the action of the air and frost for one or two winters, it is found to produce grass very abundantly.

As I believe there are some parts of the eastern states where the subsoil exists, I would be glad to be informed, through your paper, of the nature of the superincumbent soil, and of the crops which are considered best adapted to it.

I am, dear sir, your friend and servant.
R. H. ROSE.

From the Vermont Republican.

The usual method of making board-fence, to put the posts firmly into the ground, and to attach the boards to them in a direct line. But to this species of fence there has ever been a grand and insurmountable objection, viz.—That posts in a short period will rot in the ground and the fence becomes frail and decays. I have recently discovered a kind of board fence which completely obviates this material objection, a must beg leave to recommend it to the community at large. Perhaps around your gardens and near your buildings, where beauty or elegance is so far an object that you would prefer to build a new fence every six or eight years, than have a crooked one, the ordinary board fence would better comport with your feelings. But around your distant lots where you have nothing but interest to consult, and where a permanent and lasting fence is required, the one I am about to propose is by far preferable. In the first place, it is the better way to cut the logs for your boards and posts in the summer, when the bark will peel, as it is ascertained that timber cut at this period, will last much longer than that cut in the winter—and an additional inducement to cut it at this period is the value of the bark, which, in case of the hemlock particularly, will amply repay you for the trouble of cutting and peeling. The logs thus cut, after drying until the ensuing winter will become light, and be carried to the mill with much more ease and

* What makes the harvest plentiful.

city. Perhaps six or eight inches would be the right width for the boards, and the posts could be sawed about four or five inches square. After getting your posts and boards together, fill your fence crooked, or in the manner of "Virginia fence," (so called.) The posts need not stand more than two feet each way from a straight line, allowing your boards to be four or five feet long. In this way you will entirely prevent the necessity of inserting your posts in the ground, and your fence will be abundantly firm and permanent. Instead of placing the ends of your posts upon the ground, I would commend inserting beneath each post a thin stone. This will prevent any decay to which they might be otherwise exposed, by coming in contact with the surface of the ground. Fence this description will undoubtedly endure twenty-five or thirty years—three times the period that the ordinary board-fence will last, when the posts are put into the ground. It can also be made I suspect, with less expense of timber than any mode now prevalent.

In the Somerset Journal, a paper printed at Norridge-week, Maine.

Coffee.—There are now growing, in full bloom, in gardens in this town, a number of fine COFFEE PLANTS. The seeds from which these plants sprang were raised in this place the last season, from a seed which was accidentally found among some raisins. Seventy kernels were produced from one seed last year, perfectly ripe; and we should judge that on a plant in the garden of Mr. Manly, there will be considerably over a hundred. The coffee ripens and comes to maturity in about the same time that Indian corn does. If one plant will come to maturity and yield in this manner, why will not any quantity?

From the United States Gazette.

An Agricultural Society has been formed at Sydney (Botany Bay) which promises much advantage to the territory. The interior of New South Wales will ripen the orange, the lemon, the apple, that invaluable grain maize or corn, and other bounties of nature. Some idea may be formed of the increasing number of respectable agriculturists, from the circumstance of eighty gentlemen having sat down at the first dinner of the Society, when upwards of 15000. were subscribed to carry into effect the purposes of the association. An advertisement in one of the Sydney papers invites masters of vessels to pick oranges for their sea stores, from the stores of a dealer, at 6d per dozen. The same paper states that a house at Sydney is now selling tobacco "equaling the best American." Those cultivators of the vine, who have selected proper situations, have every prospect of being amply remunerated. A sample of wine made there received a silver medal from the Society of Arts. The wool of their sheep is said to be uncommonly fine.

Heat from Friction of a Solid and Fluid.—It may be remarked that the rapid rotation of the water-mills, which complete the attenuation of the liquid mixture for paper before it passes to the tub, produces in it a very sensible heat, not at all due to the elevation of the temperature of the wheel itself by the friction of its axis, for it cannot be perceived by touching that part,

but it is attributable to the blow of the fans of the wheels on the mixture, which they strike with much rapidity and violence. This is the first instance known to us, says M. Pictet, editor of the *Bibliothèque Universelle*, of heat produced by friction of a solid against a liquid.—*Ibid.*

M. Huerne de Pommeuse, member of the Chamber of Deputies, has published a comparison between the British and French Canals, in which he acknowledges, that his principal object in the first half of the published half volume, dedicated to English labors, is to stimulate the emulation of his compatriots, and to make them co-operate with government in the existing circumstances, where France has much to create, in this department. The editors of the *Bibliothèque Universelle*, in their account of this work, pleasantly observe, that the author's hope reminds them of a reply made to them in Tuscany, by a minister of state of great experience, to whom they extolled certain improvements elsewhere introduced, and which seemed to them capable of being introduced into his country: "Alas!" said he, "diseases communicate from people to people; but health, you know, is not contagious."—*Ibid.*

Canal Navigation.—The tread-wheel has been applied by M. Van Heythuysen to the propelling barges on canals. The object is to obviate the use of horses. The apparatus is made light and separable from the barge, and it is found that two men can propel a barge by it, at the rate of five miles an hour. The saving of expense of horses and track-roads promises to make this application of human power very valuable.—*Ibid.*

CURE FOR DYSENTERY.

Messrs. Editors.—The following receipt is an infallible remedy for the Cholera Morbus, or Dysentery; and I think you would do well to make it known.

Take six cents worth of Isinglass, and simmer it down in about half a pint of water, on a slow fire, till it is all dissolved, and when done, add a little milk and sugar to make it palatable. Give the patient half a cup full immediately, and a spoon full every hour afterwards. Many, I can assure the public, have found it a sovereign remedy and a radical cure. I have never known it to fail in any one instance.—*Ibid.*

ON SPRINGS OF WATER.

An abundant spring need never be expected in any country that is covered to a great depth with sand, without any stratum of clay to force it upwards, as is the case in the deserts of Arabia, and immeasurable plains of Lybia. Neither are we to expect abundant springs in any soil that consists of an uniform bed of clay from the surface to a great depth; for, it must always be in some porous stratum that the water flows in abundance and it can be made to flow horizontally in that only, when it is supported by a stratum of clay, or other substance that is equally impermeable by water. Hence the rationale of that rule so universally established in digging for wells, that if you begin with sand or gravel, &c. you need seldom hope to find water, till you come to clay; and if you begin with clay, you can hope for none in abundance, till you meet with sand, gravel or rock.

From the Belknap Falls Intelligencer.

A root of Rye (the product of a single grain) has been shown to us, which had one hundred and seven stalks. It was from the farm of Capt. Wilson, in Saxton's village. We regret that Capt. W. cut the ears from the stalks before it was exhibited; because it prevents our speaking with certainty either of the quality or quantity of the grain. The stalks are, however, large; and this surely denotes that there was at least, an average result of grain. And it may not be an unfair inference, to say, that the remarkable thriftiness of the root indicates a more than ordinary productiveness.

Timber, by the process of charring, or burning the surface, may be preserved for an indefinite time, even though exposed to damp, or buried in the earth. The utility of charring timber used for posts or water works, is so evident, that we are surprised it is not more generally attended to. The most wonderful proof of the indestructibility of charcoal timber is given in *Watson's Chemical Essays*, where we are informed "that the beams of the Theatre of Hercules were covered with charcoal, by the burning lava which overflowed that city; and during the lapse of 1,900 years, they have remained as entire as if they had been formed but yesterday. This property was well known to the ancients, as the famous temple of Ephesus was built on piles charred to preserve them from decay; and some years ago, piles were found in the Thames, charred, in a perfect state of preservation, in the very spot where Tacitus relates that the Britons drove in piles, to prevent the attack of the fleet of Julius Caesar."

Steel.—The Society of Encouragement at Paris has decreed a gold medal to M. Pradier, who has brought his steel instruments to the highest degree of perfection. He has discovered the valuable art of rendering steel very hard, and at the same time elastic. His steel blades can be bent double, and are yet so hard as to cut iron, without any injury whatever to the edge, however fine and thin it may be. This experiment was many times repeated by M. Pradier, in presence of the committee, and always with success.

Professor Gmelin, is said to have discovered, in clink-stone lava, ammonia, which is disengaged by distillation.

For Watch Makers.—Oil used for diminishing friction in delicate machinery, should be free from all acid and mucilage. The following is the process for procuring it in its most pure state. Put into a mattress or glass flask a portion of any fine oil, with seven or eight times its weight of alcohol, and heat the mixture almost to boiling; decant the clear upper stratum of fluid, and suffer it to cool; a solid portion of fatty matter separates, which is to be removed, and then the alcoholic solution evaporated in a retort or bason, until reduced to one fifth its bulk. The fluid part of the oil will be deposited. It should be colourless and tasteless, almost free from smell, having the consistence of white olive oil, and not easily congealable.

Although the following receipt has been already published in the *New England Farmer*, vol. i, page 3, we give it again at the request of some friends, to oblige new subscribers, not in possession of that volume, and to show our opinion of its utility. We have it from good authority that several persons have succeeded in making most excellent wine, by following *exactly* the prescriptions of this receipt; and some persons who have tried a number of different modes of making this kind of wine, have told us that the method here laid down is much preferable to any with which they are acquainted. We presume that the current wine vintage is not yet passed by in some places within the limits of the circulation of our paper, and hope this formula may yet be of use to some of our readers the present season.

From Carey's American Museum.

RECIPT FOR MAKING CURRANT WINE.

Gather your currants when full ripe; break them well in a tub or vat, (some have a mill constructed for the purpose, consisting of a hopper, fixed upon two lignumvita rollers) press and measure your juice, add two thirds water, and to each gallon of that mixture, (i. e. juice and water) put three pounds of muscovado sugar, (the cleaner and drier the better; very coarse sugar first clarified, will do equally as well,) stir it well till the sugar is quite dissolved, and then turn it up. If you can possibly prevent it, let not your juice stand over night, as it should not ferment before mixture.

Observe that your casks be sweet and clean, such as never had either beer or cider in them, and if new let them be first well seasoned.

Do not fill your casks too full, otherwise they will work out at the bung, which is by no means good for the wine; rather make a proportionable quantity over and above, that after drawing off the wine you may have a sufficiency to fill up the casks. Lay the bung lightly on the hole to prevent the flies &c. from creeping in. In three weeks or a month after making, the bung hole may be stopped up, leaving only the vent-hole open till it has fully done working, which generally is about the latter end of October. It may then be racked off into other clean casks if you please; but experience seems to favor the letting the wine stand on the lees till spring, as it thereby attains a stronger body, and is by that means in a great measure divested of that sweet luscious taste, peculiar to new made wine; nay, if it is not wanted for present consumption, it may without any damage stand two years on the lees.

When you draw off the wine, bore a hole, an inch at least above the tap-hole, a little to the side of it, that it may run clear off the lees.—The lees may either be distilled, which will yield a fine spirit, or filtered through an Hippocrates' sleeve and returned again into the cask. Some put in spirits, but I think it not advisable.

Do not suffer yourself to be prevailed on to add more than one third juice as above prescribed, in hopes that the wine may be richer, for that would render it infallibly hard and unpleasant, nor yet a greater proportion of sugar, as it would certainly deprive it of its pure vinous taste.

By this management you may have wine, letting it have a proper age, equal to Madeira, at least superior to most wines, commonly imported, and for much less money.

In regard to the quantity of wine intended to be made, take this example, remembering that twelve pounds of sugar are equal to a gallon of liquid.

For instance, suppose you intend to make 30 gallons, then there must be,

8 gallons of juice,	24 gallons of mixture,
16 of water,	3 multiplied by,
24 gallons of mixture,	12) 72
6 gallons from sugar.	equal to 6 gallons of
30 gallons.	liquid.

and so proportionably for any quantity you please to make.

The common cider presses, if thoroughly clean, will do well in making large quantities: the small hand-screw press is most convenient for such as make less.

N. B. An extraordinary good spirit for medicinal and other uses, may be distilled from currant juice by adding a quart of molasses to a gallon of juice, to give a proper fermentation.

NEW ENGLAND FARMER.

SATURDAY, AUGUST 16, 1823.

MR. ROSE'S COMMUNICATION.

We hope our friend will pardon us for giving his letter (published in this day's paper, p. 20,) at full length, without his licence, either expressed or implied. A good patriot may sometimes be allowed to trespass a little on private property, provided he can thereby benefit the public; and by parity of reasoning, a private letter may be published without the consent of the writer, if it contain information which may prove useful to the community. That part which relates to our own "reminiscences," could not well be separated from the rest without injuring the texture of the article. We therefore concluded to publish the whole instead of "an extract of a letter," &c. according to immemorial usage, although we are sensible that we run some risque of being accused of egotism in thus obtruding upon our readers, some allusions to a portion of our editorship's biography, our propensity to poetizing, and other things which have no connexion with what should be the objects of an agricultural paper.

We perfectly agree with Mr. Rose in the opinion that the *kind of soil* on which agricultural experiments are made, ought to be specially noted in giving accounts of such experiments; otherwise we shall often derive no benefit from details of agricultural processes. Every farmer can give a description of his soil accurate enough for most purposes, without any knowledge of chemistry, though he may not be able to state the exact proportions of clay, sand, lime, &c. of which it is composed. We intend shortly to give in our paper the different modes of analysing soils recommended by writers on husbandry, which may enable the owner of land to tell with sufficient exactitude for all possible practical purposes, what kind of land, chemi-

cally considered, his farm, or any part of it, is composed of. He may then adapt his plants to his soil, instead of attempting to force his soil to bear plants to which it is not adapted.

We hope that our New England cultivator will be induced to copy Mr. Rose's example and send us the results of their analyses of soil in different parts of the country. Those who wish for information relative to the mode of conducting processes of this kind, may find method, taken from the writings of Mr. John Young, of Halifax, Nova Scotia, entitled "*Lectures of Agriculture*," and republished in our first volume, page 91. This article we intend to publish again for the benefit of new subscribers who may not be in possession of our first volume, together with other means for obtaining the same end (as before intimated) copied from other approved authors.

Some philosophers, if we mistake not, have maintained that lime is exclusively the product of animalization, and Judge Cooper's assertion (mentioned by Mr. Rose, and quoted in No. 17, vol. i, of our paper,) that some fine pasture lands in Pennsylvania contain not a particle of lime would seem to corroborate that theory; for if there is no lime in the soil, and the bones of animals fed upon it contain lime as usual, it must follow, we believe, that animal organization can change other substances into lime.—But Mr. Rose's analysis overturns this theory, so far as it depends on Judge Cooper's assertion that no lime is to be found in the soil of this fine grazing country. We have the highest respect for Judge Cooper's authority on scientific topics, but cannot carry our reverence so far as to suppose him altogether exempted from error, especially as regards facts, which he probably derived from the testimony of less accurate observers.

We hope that Mr. Rose's communication will prove what we farmers call an *entering wedge*, for other articles from the same source. We know him to be abundantly able, and hope he will be no less willing to contribute to the objects of our establishment the fruits of a highly cultivated intellect, united, we believe, with an acquaintance with the art as well as the science of agriculture.

COMMUNICATED.

Simcon Draper, Esq. of Brookfield, has a calf of the Holderness breed, which weighed at three months old 332 pounds, and at four months, July 14th, 440. The gain for the last month is over 3 1-2 lbs. per day. Brookfield, July 19. A SUBSCRIBER.

A lemon raised by Mr. Adam Price, at Burlington, N. J. measuring 12 inches in circumference and weighing 14 ounces, has been shown in New-York. The tree from which it was gathered had on it at one time this season above 150 lemons, many of which were nearly as large as the above.

The industrious Mr. Osgood, of South Salem, is now gathering in his currant vintage. He will make about 1000 gallons of wine this season. His wine has sometimes sold at the South for \$3 a gallon.—*Salem Gas.*

FOR THE NEW ENGLAND FARMER.

Mr. Editor—I think there is an error in a commendation given in your paper of the 12th inst., carefully to pick from loamy soil all the ones as far as it could be done. The object could be directly the reverse.

I was in the habit of having the stones picked out light and loamy soil in this careful way, under the idea that it was beneficial, and considering them as worse than useless and troublesome. An excellent practical farmer in my neighborhood, suggested to me that I was in error, observing, that he picked no stones from light or loamy soil, except such as the roller, laying the ground down, would not press well with the earth, and that he thought it could be well if even these were sunk in the soil by labor.

I have so practised, and am well convinced that both utility and economy are promoted by all stones being covered and intermixed in the soil. The following are some of the reasons for my opinion.

1st. Stones absorb moisture and give it back to the earth in slow degrees, as is most conducive to the purposes of vegetation, and when stunted.

2d. They keep land light and cool, which is for the soil we describe, a great advantage.

3d. It is thought that from the calcareous and other substances of which they are composed, they impart, as they are worn upon and ground in culture, a fertility to the soil.

4th. In fact, stones are of no other disadvantage, probably, to any soil, than when they incumber the surface. If taken from low soil and situations, you do an injury by sinking the ground which would be raised to advantage.

I am sensible I differ from a member of a respectable Society in a neighboring state; but I speak from some experience of my own, and it is of more consideration, from the judgment and opinion of those who have been rendered judicious observers.

I am yours, &c. W.
Dorchester, August, 1823.

FOREIGN.

The last news from Europe is from London to the 1st and Paris to the 27th of June, and Gibraltar to the 10th of July. It should seem by these advices that French troops are overrunning Spain with rapidity, and almost without meeting with opposition. I entered Port St. Mary's on the 23d of June, to the amount of 4,000 foot and 500 cavalry. St. Mary's is nearly opposite Cadiz, distance less than three miles, the nearest points of which South threw shell into in Bonaparte's war with Spain.

Malusia is occupied by 29,000 men, of whom 5000 cavalry, and 14 pieces of cannon. They formed divisions which united at Cordova.

5th. Ballasteros, according to French accounts, had compelled to evacuate Valencia. His retreat, say, was so precipitate, that he lost a column of 2000 men, which had been despatched to him.

The only hope now is that Cadiz will be able to hold out, and a few months resistance will do every thing for Spain, as the French must retreat across the Pyrenees before December, or submit to undergo a winter campaign.

English paper states that it was reported in the letters from Paris that the Spanish Cortes had proposed to the Duke of Angoulême, to give up the custody of the King, provided their personal safety shall be guaranteed.

The London Courier states an opinion that Sir Wm. Pulteney, British Ambassador to Spain, has been or-

dered to return home. Follow the King he cannot, for that would be to sanction the violence which has been offered in removing him; acceded to the Madrid Regency he cannot be, for that would be a virtual abandonment of British neutrality.

The Paris papers say that the garrisons of St. Sebastian and Santona, are reduced to the greatest difficulties, and must soon surrender, the men having only six ounces of bread per day.

A letter from Bayonne states that there are many reports at Madrid of an approaching arrangement; but even if the Cortes should agree to such a one it would remain to be seen whether Mina, Ballasteros, Villacampa and Morillo would subscribe to it, as it must be confessed that there are elements sufficient to continue the war, and that the French will want in that case an addition of 50,000 men, and large sums of money.

DOMESTIC.

Perkins' Steam Engine.—The New York Statesman says it is reported that an American gentleman in London has bought of Mr. Perkins the right of navigating the waters of the states of New York, New Jersey and Pennsylvania, for the sum of forty thousand dollars.

The Sea Serpent has been seen on the 6th and 7th inst. near Gloucester. At Sandy Bay Harbor he remained for some time visible, within fifty yards of the shore, and was fired at a number of times with muskets; two balls were seen to strike him and rebound. He was seen by as many as fifty people, being perfectly calm, with his head about two feet out of water, and his body visible only in parts or humps, with a space of about two feet between each. The inhabitants of Sandy Bay, who saw this monster, are desirous of withholding their testimony on the subject, as they conceive their reputation for veracity has been heretofore too much trifled with.

The country between Darien and Savannah, in Ga. has been inundated by rain, which commenced falling on the 22d July, and continued almost without intermission for 27 hours. The mail from Darien to Savannah was transported some distance in a canoe, while the stage horses swam along side. It is supposed that not a bridge, large or small, is left between Bryan Co. and Darien. At Baiden's Bluff, a large Academy had been swept off entirely into a gulf, and nothing but the roof was visible.

Gen. Warren's Sword.—The Belfast, (Maine) paper says, "we have recently received a number of documents tending to prove that Capt. Cornelius Dunham, of this town, purchased of a British officer's servant, at Halifax, the identical sword which Gen. Warren wore when he fell. The sword is now in the care of Wm. Davis, Esq. of Plymouth, Mass."

House of Industry.—The directors of the House of Industry, at South Boston, have appointed Mr. William Stone, of Watertown, Superintendent, with a salary of \$500 per annum. The house having been made ready for the reception of tenants, forty-one persons were, on Thursday last, discharged from the Alms House, for the purpose of being removed thither, but twenty-one of the number, thinking that if they must get a living by industry, they might as well labour on their own account, took an absolute discharge. The other twenty were transferred to the House in South Boston, and we are told, have found it a more agreeable residence, and the occupation less irksome than they expected. They are to be followed, we understand, by other tenants of the Alms House, the number of whom still remaining, is about 280.—*Daily Adr.*

A man named Joseph Danford, of Boston, while on a visit to the Navy Yard in Charlestown, on Sunday last, fell from the deck of a 74, now on the stocks, and was instantly killed.

Conviction of a Pirate.—Barbadoes papers have been received at Baltimore to the 15th July. A Court of Vice Admiralty was held at Barbadoes on the 14th, at which a man of the name of Johnson, was tried for and convicted of murder and piracy. It appears a Columbian privateer had captured a Spanish brig and put a crew on board with orders to proceed to Laguiria. Johnson was one of these, and he and the prize master

murdered at different times the whole of the crew except two. Johnson then fastened the prize master to the deck where he died in two days. On being asked at Barbadoes where the different persons of the crew were, he without hesitation answered, "I shot them."

The inhabitants of the village of Wooster, Ohio, were lately galled by a "raw-boned athletic-made fellow," who offered to give them some pleasing experiments of the nature and powers of exhilarating gas. He collected a pretty numerous assemblage of both sexes, at the rate of 25 cents a pair. After many of the company had sucked and tugged away at his gas-bag till they were exhausted, without any effect, it all at once popped into their heads that he was a *yankee*; and he was accordingly taken before a justice and examined; he confessed that he was no chemist, and had merely got a gas-bag for the purpose of "raising the wind." While they were cogitating and planning some punishment answerable to his crime, he slipped through the fingers of the guard, and fled into a neighboring thicket, leaving his "bag and baggage" behind, and we guess he'll trouble them no more.

HARVEST HOME.

Written for *Ruley's Vocal Melodies*, by S. Woodworth.

When mellow autumn yields
All her golden treasures,
Then those who dress'd the fields,
Partake of harvest pleasures.
This, lads, is Harvest Home,
Those who labor daily,
Well know 'tis sweet to come,
And pass the evening gaily.
Then let each heart beat light,
Here's no room for sorrow,
Joy holds her court to night,
Care may call to-morrow.

Now Labor wipes his brow,
Rest and plenty wait him,
Barn, cellar, rick and mow,
Are fill'd to recreate him.
Scythe, sickle, rake and hoe,
All are now suspended,
Like trophies in a row,
For future use intended.
Then let each heart beat light, &c.

Now gay Pomona's store,
Past exertions blesses;
Rich streams of nectar pour,
Sparkling from her presses.
Full goblets, streaming board,
Crown the farmer's labors;
These real bliss afford,
When shar'd by jovial neighbors.
Then let each heart beat light, &c.

From the New Hampshire Literary Journal.

MESSRS. EDITORS.—In the dry and cold summer of 1816, in the latter part of June, I was informed that a well about three or four miles distant was frozen in such a manner, that no water could be obtained from it. On the fourth of July, with some others, I called to ascertain the fact; and we found it *completely frozen over*, and no appearance of water, except perhaps a quart in a small hole, which had been cut in the ice. On the 19th of the same month, I called again to examine it. The ice had now become detached from the stones, and fallen down to the water, which was lower than when the ice formed. The block of ice at this time was about the size of a common wash tub. On the 25th, I found it had all dissolved. This well is in the town of Lyman, in the county of Grafton, at the north-east corner of a house belonging to Daniel Moulton, Esq. occupied by Stephen Smith. It is situated on high land, 5 or 6 hundred feet above the level of Connecticut river, and about 3 miles distant. The depth of the well is from 12 to 15 feet; and from the surface of the ground to the ice was about 8. It was perfectly open the whole season, and exposed to the action of the atmosphere.

In the same town, and adjoining Connecticut river, is a plain, which, in its natural state was covered with pine and hemlock. This plain is elevated 80 or 100 feet above the bed of the river. In the year 1815, about fifteen or twenty acres of this timber was felled, and on the 3d day of July, in the following year it was fired, and burnt in such a manner that scarcely any small stuff was left. On the 10th day of the same month, I was passing across said plain, and the owner of the burnt land, who was at work thereon, showed me a log which he had

just removed from its bed, and which was frozen down, about 4 feet in length, and 8 or 10 inches in breadth; I saw the ice cut up with an axe, and it appeared solid as in winter. There was nothing to shade the spot where the log lay, there being no standing timber within 30 rods of it.

These facts, which may tend to show the extreme cold of that season in this vicinity, are well known to many individuals; and you are at liberty to notice them in your Collections.

CALEB EMERY.

Lyman, N. H. July, 1823.

A TIGER IN KENTUCKY.

The Lexington, Ky. Gazette of the 17th inst. contains the following account of a strange animal which has been recently seen in that state:—

We learn from Russellville that a gentleman discovered an animal of alarming appearance, a few miles from town, and hastened to the nearest house where he was joined by three men, two of whom were armed with guns, and attended by a dog. The strange monster was again discovered, and while bayed by the dog, the two guns continued to fire on him at the distance of about fifty yards without forcing him to move from his stand: a furious look, and appalling brow frightened the two men without guns who fled to town. Experienced marksmen continued to fire, and on the twelfth shot the beast put off at full speed, marking his way by blood flowing from many wounds that it must have received. The dog was too much frightened to continue the pursuit, and the huntsmen dare not venture, although one of them was as fearless as Boone himself, and accustomed to the chase from early life.

When the news reached Russellville about forty gentlemen repaired to the spot, and had a full view of the ground. The print which the paws of this animal made in the earth corresponds with the account given of his great bulk by those who had an opportunity of viewing him at a short distance for several minutes; he was of a brindle color with a most terrific front—his eyes are described as the largest ever seen in any animal. We are well acquainted with the party engaged in the attack, and give the fullest credit to the account we have received.

The conclusion drawn is that the animal in question was a Tiger of the largest order from Mexico, and that it is like monsters of the deep, thought proper to wander into distant regions. There is nothing remarkable in his passing such a distance unobserved. Wolves have been seen of late years low down in the northern necks of Virginia, a distance of nearly 200 miles from the Blue Ridge, the supposed residence of those animals; they had to pass through a country of the thickest population unprotected by large forests until they arrived on the Potomac river where cedar and pine thickets shelter them from all future danger.

The above Tiger was seen a few days after braving a dozen shots and making its way into the state of Tennessee, and there is still a prospect of its being taken and the people gratified with a more correct description.

From the Philadelphia Gazette.

We all recollect the story of the Lacedemonian matron, whose joy at her countrymen's ob-

taining a victory, was so great, that she could not lament the loss of her children slain in battle. The following anecdote, extracted from Thacher's Military Journal, displays equal patriotism in conjunction with true paternal affection, and consequently places the American father above the Spartan mother.

"A venerable old man had five sons in the field of battle, near Bennington, and being told that he had been unfortunate in one of his sons, replied, What, has he misbehaved, did he desert his post, or shrink from the charge? I, sir, says the informant, worse than that, he among the slain, he fell contending mightily the cause. Then I am satisfied, replied the good old man; bring him in, that I may behold him, and survey the darling of my soul. To which the corpse was brought in and laid before him. He then called for a bowl of water and a napkin, and with his own hands washed the gore and dirt from his son's corpse, and wiped his gaping wounds, with a complacency as he himself expressed it, which before he never felt or experienced."

The story is simple and touching.

Pleasure, like an over-fed lamp, is extinguished by the excess of its own aliment. But the lovers of pleasure are not always prudent, even upon their own principles; for we are persuaded that the world would afford much more satisfaction than it does, if we did not press, torture, and strain it, to yield what it does contain: much good, and much pleasure, it does liberally bestow; but no labor nor art can extract from it that elixir of peace, that divine sense of content, which it is not in its nature to produce. There is good sense in searching to every blessing for its *hidden* properties; it is folly to ransack and plunder it for such the experience of all ages tells us are *foreign* to it. We exhaust the world of its pleasure, and then lament that it is empty; we wring the pleasures to the very dregs, and then complain that they are rapid.—*Providence American.*

Yellow fever.—The following circumstance is a remarkable instance of the non-contagiousness of the Yellow Fever. It is translated from *Revue Encyclopedique* for January last:—A young Englishman, who arrived at St. Thomas's with a young and beautiful countrywoman whom he had secretly married, was attacked by the yellow fever. When the disease was at its height and symptoms of inevitable death became apparent, the young woman, in despair, and determined not to survive the object of her affection, undressed herself *entirely* and placed herself beside her dying husband in bed, embracing his body. She remained for ten hours in this situation, and with difficulty removed after he had breathed his last. She did not experience the slightest symptom of the disease.

U. S. Gazette.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLAR ANNUM, payable at the end of the year—but if who pay within *sixty days* from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at discretion of the Publisher) until arrearages are paid.

Agents who procure seven subscribers, and come responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

NEW ENGLAND FARMER.

Vol. II.

BOSTON, SATURDAY, AUGUST 28, 1823.

No. 4.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

RYE.—The farmer, who has it in his power to drive his business, instead of being driven by it, will do well to sow his winter rye some time between the middle of August and the middle of September. If it be sowed so early it will be less apt to winter-kill, will require less seed, the growth will be stouter, and the produce enter, other things being equal, than if the sowing was deferred till late in autumn. Some foreign writers on agriculture assure that winter-rye and spring-rye are of the same species; and the Farmers' Assistant says there is but one kind of rye; but this may be winter-rye or spring-rye, by gradually changing it to different times of sowing.—Take winter-rye, for instance, and sow it later and later each fall, and it may at length be sown the spring, and become spring-rye. On the contrary, sow spring-rye very late in the fall at last, and you may gradually sow it earlier each year, until it may be sown in May, and used the next season for pasture, or mowing, and then sown to perfection the second year." The same opinion is likewise expressed in Deane's New England Farmer.

Rye is capable of being cultivated on most kinds of land, but the light sandy soils, where wheat will not thrive, are the sorts of soil on which it will, generally speaking, be found most profitable to raise this kind of produce. John Sinclair observes that "this species of grain is not so extensively cultivated in Scotland as it ought to be, (for weighty crops of it might be raised on soils of the most porous and nature, and upon almost pure sand along the sea shore;) and the winter sort, without which the people living on the coasts of the north could hardly be subsisted, is almost unknown. A correspondent informs me that he had 35 bushels of rye per English acre, on a soil that would not have produced 20 bushels of oats. Indeed, oats, sown along side of the rye upon the same field, and on land as nearly equal as could be judged of the same quality, were scarcely worth the expense of reaping. On rich land, rye has been found a more certain crop than oats. Mr. George Culley remarks that rye, like oats, will answer in crude soils without lime, or calcareous manures, which others that crop peculiarly calculated for waste lands when first brought into cultivation."

Soils which will produce tolerable crops of wheat had better be cultivated for the purpose of raising wheat than rye. And, if we may believe what English writers tell us relative to the subject, the use of lime for manure will only so far change the nature of a poor soil as to make it more fit for rye, than wheat may be made to cultivate. Mr. Marshall, in his *Rural Economy of Berkshire*, says "before the use of lime was prevalent much rye was grown on the lighter soils upon the margin of the Vale, and in the lands scarcely any other crops than rye and oats were attempted. Now, rye is principally confined to the Moorland-lands; and even the alteration of soils by lime has been

such that wheat has become the more prevalent crop.

"Nevertheless on light, sandy soils, rye is generally more profitable than wheat, and the bread which is made from a mixture of the two grains is here esteemed more wholesome to people in general than that which is made from wheat alone."

When rye is sown upon light land, it ripens much earlier than on a cold stiff ground, and it is said by some writers that by continuing to sow on such a soil for two or three years, it will be forwarded so much as to ripen a month earlier than that which has been raised upon strong cold ground. For this reason, those who sow their rye late will do well to provide themselves with this early seed.

Dr. Elliot informs, that if rye be sowed successively every year upon the same land, both the crop and the land will be greatly improved, inasmuch that some grounds, which would yield but five bushels to the acre at first, have in time produced a crop of fifteen bushels, without the charge of manure, and Dr. Deane observed that he "had known the same spot produce twenty crops of this grain in succession, excepting that it was planted with Indian corn once or twice, to subdue the weeds, and that the crops yearly increased instead of diminishing." But this, it is said, will not be the case, unless the soil is naturally of a good quality, and the stubble be completely turned under immediately after reaping. If the ground is suffered to remain after harvest without being ploughed till the stubble is dried and shrivelled so that it possesses but little substance, and the seeds of weeds have had time to ripen, the crops of grain in each succeeding year will be diminished, and the weeds will take an almost exclusive possession of the soil.

The Farmers' Assistant is opposed to the raising of successive crops of rye, unless as much as twenty-five bushels of this grain can be yearly had from the acre; as such an annual product would probably afford a clear profit to the acre of half that number of bushels; and such a profit, he observes, in some of the lighter, and in some of the harder kinds of soils is not to be despised. The same writer recommends sowing winter-rye and spring-rye alternately, in order that the ground might, every other year, be enriched by the application of gypsum. "The growing crop of rye," he says "receives no benefit from the application of this manure; but it quickly covers the ground with a fine sward of white clover; and as soon as the ground is thus swarded, it is in good condition for bearing any crop. Let the gypsum, therefore, be sown in the spring, on the growing crop of winter-rye, and by the middle of October following, the ground will be covered with white clover; turn this sward over in the latter end of the fall, and in the spring sow a crop of spring-rye; and, as soon as this is taken off, turn the ground over again for a crop of winter rye; and in the spring repeat the process of manuring with gypsum as before, for a crop of spring-rye, and thus proceed with these crops alternately."

Some sow their winter-rye at the last hoeing of Indian corn, and hoe it in; and this Dr. Deane observed was a good practice when it is sown on flat land, or on a rich or heavy soil, where grain is apt to suffer by the frost of winter. For the plants of rye will be mostly on the corn hills, and so escape injury from frost; at least they will most commonly escape, or so many of them as are necessary to give a good crop. The plants that are killed will be those in the low spaces betwixt the hills.

Rye is not only a proper crop on land which is too poor to produce a good crop of wheat, but it should be sown on a soil which is very rich, in preference to wheat, because it is less apt to grow so rank as to lodge, or blast, than wheat. It is a very suitable crop for drained bogs. In the first volume of Communications to the British Board of Agriculture, page 311, in speaking of the culture of rye in Russia, it is observed that the produce from boggy lands drained and sowed with rye is upwards of forty bushels to one sowed, and they generally use a much smaller quantity of seed in sowing such lands. Another proof that rye will bear very plentiful manuring, may be adduced from a case reported by Mr. L'Hommédieu, of New York, who observed, in substance, that a neighbor of his manured twenty square rods of poor, gravelly, dry soil, with four thousand Menhaden fish, and sowed it with rye, at the rate of about one bushel to the acre. In the spring it was twice successively eaten off, close to the ground, by sheep breaking in, after it had acquired a height of nine inches the first time, and six inches the latter. These croppings, however, only served to make it grow thicker and stronger than before; and when harvested it produced sixteen bushels, or at the rate of one hundred and twenty-eight bushels to the acre; giving to the owner, according to the calculation of Mr. L'Hommédieu, at the rate of eighty-five dollars to the acre of clear profit.*

In the Memoirs of the New York Board of Agriculture, vol. i, page 82, it is said, "Rye should be sowed the last week in August, or the first week in September, at the rate of about thirty-six quarts per acre, some say forty-eight quarts. But if it is not sowed at that time, it ought to be delayed until late in November, so that it may not come up until spring. A. Worthington had a good crop, which he sowed in a January snow storm. Rye raised on upland makes much better flour than that which is raised on low or damp land."

Rye may be sown in autumn to great advantage for green fodder for cattle and sheep, particularly the latter, in the spring. Ewes and lambs will derive much benefit from it, at a time when little or no other green feed can be procured. When it is meant for this purpose it should not only be sowed early in autumn, but should be sowed thicker than when it is intended to stand for a crop of seed. Some say

* Transactions of the N. York Agricultural Society, part 3, pp. 35, 36. This account may seem incredible, but Mr. L'Hommédieu declared that it was attested to by many credible witnesses.

that it may well be mowed for hay two or three times in the course of the summer, and this piece of husbandry is recommended for farmers whose lands are mostly dry or unsuitable for grass.

The quantity of seed to be sown on an acre should vary according to the soil, the time of sowing, and the purposes for which it is intended. If it be sowed in the latter part of August, or beginning of September, and is intended to remain for a seed-crop, the quantity should vary from 32 to 49 quarts, according to the goodness of soil. Later sowing requires more seed, and in some cases two bushels to an acre will not be too great a quantity. Bannister's Husbandry says, "when this grain is sown for sheep-feed, it is proper to allow three bushels to the acre, for where the blade, haum or stalks form the primary object, a much larger proportion of seed is requisite, than when the crop is meant for harvesting."

Although the following able article has been already pretty extensively published in newspapers and other periodical publications, we are induced to transplant it into our columns. It contains the best instructions we have seen on the important topic of which it treats, and we think should compose a part of every farmer's library, and be referred to in every stage of the culture of a crop which may at no distant period form one of the most valuable staples of New England. The machines which have been lately invented for dressing Flax, without the trouble and expense of water or dew rotting, promise to obviate the principal obstacle to its general culture; and should the expectations of those best acquainted with those machines be fully realized, we see nothing to prevent Flax being as profitable a staple of the Northern, as Cotton is of the Southern parts of the Union.

From the Massachusetts Agricultural Repository.

ESSAYS ON FLAX HUSBANDRY.

BY S. W. POMEROY, ESQ.

First Vice President of the Massachusetts Society for Promoting Agriculture.

No. 1.

The great surplus and depressed prices of our chief agricultural products, render it necessary for the farmer to seek others upon which he may calculate for more profitable returns, or at least such as will constitute a division of his risk; with this view Flax may be presented as an item deserving particular consideration.

For twenty years preceding 1816, the annual export of Flax Seed from the U. States, averaged but about two hundred and fifty thousand bushels! When they were British colonies, with one fifth of the present population, and a territory under cultivation probably much less in proportion, there were exported in one year (1770), upwards of three hundred and twelve thousand bushels.* It is very obvious that the causes of this decrease, which exhibit such a contrast to the increase of all other products of the soil, may be attributed to the introduction of

vast floods of cotton fabrics and yarns, at prices (nominally) very low, and the unexampled demand for breadstuffs and other food, during the period referred to. The effect has been to place flax farming so far in the back ground, as scarcely to attract the attention of agricultural societies, when engaged in promoting improved methods of cultivation for other crops, and also, it is feared, to curtail household manufactures, the extension of which, it will not be denied, is eminently conducive to the prosperity of an agricultural people. For although prudent farmers have usually a small patch, the object has been so inconsiderable as not to demand any particular care in its management, and a tolerable crop, which, in Europe, is considered as certain as any they raise, is supposed in many districts to be the effect of chance, or, as it is termed good luck. We will not pretend that Flax was at any period in this country estimated as a profitable, though formerly a necessary crop. But it is presumed, such has been the acquisition of knowledge, and improvements in agriculture, and especially those branches of mechanical science connected with it, that an entire new view may be taken of flax husbandry—that it may be made to enter into the agricultural system of the country much more extensively than heretofore, and possibly be ranked as a considerable, and not unprofitable staple. With these impressions I have devoted some attention to the subject, and shall submit such information as I have been enabled to collect from various authentic sources; together with some remarks and intimations, which, should they throw no light on the question, may promote inquiry, and induce others, possessing better qualifications and more experience, to pursue the investigation.

My attention was drawn to the present object, in consequence of viewing the manufactories of sail cloth in Paterson, near the falls of the Passaic in New Jersey, the last autumn: where I was informed that six thousand bolts of Duck had been made for the Navy, the year preceding, of a quality superior to what I was prepared to expect, and which is pronounced, by those experienced in nautical affairs, to be worth, for service, from thirty to fifty per cent. more than canvass imported from Russia!—Indeed the respectable and liberal proprietors of those establishments are entitled to great credit for the perfection of this article; it is presumed they have conformed to the particular stipulations of their contracts with the commissioners of the navy board, who in this instance, as in others, are conspicuous for their attention to those minute details so necessary to insure solidity and permanence to what pertains to that department. But the political economists, and perhaps some farmers of the U. States, will be surprised when told, that "the flax from which this sail cloth was fabricated, was imported from Ireland and the Baltic: that if a sufficient quantity of native growth, could have been procured (which was doubtful) it does not possess sufficient strength to make such canvass as the navy board would, or ought to have been satisfied with!" The question occurs, What is the cause of this inferiority? It will not be pretended, we believe, that there is any inherent defect in the soil, or that the climate is uncongenial to its perfection. On the other hand it will be admitted that there is no

thing so peculiarly favorable, as to require less attention and care in the cultivation, than is bestowed in those countries in Europe, where it forms an important agricultural staple, & where similar management would unquestionably produce the same effects; for, however plausible the prevalent opinion may be, that the inferiority of American flax is owing solely to the injudicious preparation by dew rotting, and we grant it is one very prominent cause, still there are others, which will be noticed in the sequel, and may be considered as having a very powerful influence in deteriorating the quality, well as lessening the product.

The common flax plant (*Linum Usitatissimum*) possesses habits more peculiar than any other within the range of our cultivation; and it may be useful, in order to reconcile the farmer, at least to impress on his mind the importance of attending to those habits, to trace this plant to its native soil, or rather to the country where it was acquired by cultivation, for a vast series of ages—for it is not improbable, that, like the small grains, its present appearance is essentially different from that in its indigenous state, but to which it seems to be returning, in some parts of our country, by gradations less imperceptible, than it may have originally advanced.

Linum is mentioned at a very early period in sacred history as the production only of Egypt. The most ancient and credible author of profane history* speaks of its remote antiquity being peculiar to that country; and those writers who treat of the fabulous ages, ascribe the culture of Flax and invention of spinning and weaving to Isis, a queen of Egypt; the Ceres of the Greeks, to whom they attribute the discovery of bread corn. But if there was any question on this point, the habits of the Flax plant, in its most natural soil to have been on the margin of a river annually inundated, subside exactly at the period of seed time, leaving entire new soil, or, by forming new combinations, completely renovating the old, which becomes dry, mellow and friable at top—retaining, or having conducted by art, sufficient moisture at bottom, aided by copious dews, to insure its maturity, but never any an or storms beat it down! Where could this plant have found such a location but on the banks of the Nile? It has degenerated when transplanted to any other country, probably in proportion to want of care and attention to assimilate the soil, and gratify that impatience of change, to which it has been so long habituated. Hence it is that flax owes the reputation of being the most exhausting of all crops. Let us inquire to what extent it may be well founded.

Sir Humphrey Davy remarks, in his elegant lecture on agricultural chemistry, that "it is proved by facts stated in his seventh lecture that plants require different materials from soil, and that particular vegetables require peculiar principles to be supplied to the land which they grow." And, "as a most remarkable instance of the power of vegetables to exhaust the soil of certain principles," he states "that Mushrooms are said never to rise in successive seasons on the same spot." He may have cited Flax, as another instance not less

* Herodotus, Euterpe, chap. 37, 105.

† The inundation of the Nile begins to decrease about the 20th of September. The seeds are sown, and crops perfected while the sun is in the Southern

* Pitkin's Statistical View

markable! These facts are further substantiated by the effect produced on the soil, where old fruit trees have grown, in retarding the progress of young trees of the same family or species; for instance, a young cherry tree planted on the spot from which an old one had been dug up, will remain nearly stationary for a length of time with the highest cultivation; remove it to a spot that has been occupied by an old pear tree, and plant a young pear tree in its place, and both will immediately become as flourishing as if no tree had ever been produced on the land. Of this fact I have experienced the most complete demonstration repeatedly within the last twenty years. It is moreover, well known to many farmers, that an Apple Orchard will not succeed on land that had before been occupied by one, but that cherry or peach trees will grow vigorously on such land.

From these premises very potent arguments might be drawn in favor of a regular rotation of crops, and against summer fallows. They are here introduced to shew, that although a single crop of Flax will so exhaust the soil of certain principles,* that a repetition cannot take place with any prospect of success, even with large quantities of manure, under a lapse from four to eight years, according as "those materials" necessary to its growth may be more or less retained or supplied, yet it does not follow that the soil is exhausted of the food necessary to promote the luxuriant growth of other plants! The soundness of this position is supported by the usual practice in Europe and this country, of sowing clover and grass seeds with flax, which is considered not more exhausting, and a better protecting crop than Oats or Barley; and it is probable the result may be similar if we extend the inquiry, but it is unimportant at present, for good husbandry will ever state that clover or grass should be the next use in rotation to Flax.

We necessarily look to Europe for instruction in flax husbandry, and first turn to Ireland, where it was introduced, or rather revived in 1766, under the patronage of William the 3d, 4th years after he left Holland, to wield the British sceptre. "An able and impartial enquirer" computes that in less than forty years from that period, the home consumption and exportation of Linen, amounted annually to one million sterling," which, if we allow for the difference in the value of money, may be added to ten millions of dollars at present, "and from thirty thousand acres of land; employing, in raising and manufacture, one hundred and seventy thousand persons." When trade was in its infancy, the Dublin Society instituted for its promotion, and some years ago published several tracts on the culture of flax; from which, and from the tour of Arthur Young, in that country, we derive some important facts, yet upon the whole, less information is obtained that is applicable to the management of this country, than we were led to expect, owing to the minute subdivision of the land among the cultivators (a cotter seldom occupies more than a quarter of an acre) the very different difference of climate, and, above all, the common fertility, which Sir H. Davy, in his lecture, attributes to the proximity of the strata to the soil, in that moist climate.

But Mr. Curwen, long a distinguished statesman in the British parliament, and who, as an agriculturist, ranks with Mr. Coke and Sir John Sinclair, made a tour throughout Ireland in 1813 "with views directed to its agriculture and rural population," and to investigate the cause of the misery and degradation of that noble spirited, generous, but mismanaged people, remarks that "he does not think the causes assigned by Sir H. Davy for the superior fertility are at all satisfactory, that those demi-tints, which in England distinguish lands that are exhausted, are in Ireland almost unknown; the verdure is everlasting and luxuriant, arising, as he should suppose, from some inherent quality of the soil, which keeps it in a proper state to admit the salutary influence of the atmosphere; that the richness of the surface resists all the efforts of man to sterilize it," and he gives the Irish credit for being very persevering in their endeavors for that purpose.*

Notwithstanding this extreme fertility, Mr. Curwen says, that the Flax seed raised in Ireland was supposed to produce inferior plants, and that the Linen board of the Dublin society took charge of the importation of foreign Flaxseed for the supply of those who could not otherwise obtain it. This information relates to one of the most important features in flax farming—Change of Seed, which will be considered in our next essay.

* Observations on the state of Ireland, by J. C. Curwen, Esq. M. P.

From the Charleston (S. C.) Gazette.

Chopzigar Cheese.—The high flavor and fine color of this Cheese, which is a great delicacy, when grated and eaten with bread and butter, are derived from the plant *melilot*, a species of trefolium, which by the assiduity of Dr. Brown, (the brother of the Senator from Louisiana) has been introduced into our western country. We therefore have a fair prospect of our soon eating this relishing and economical food, of native produce.

☞ The *melilot* mentioned in the above article, is the *Trifolium Officinale* of Linnaeus.—In its general appearance it resembles the common red clover. It grows two feet or upwards in height, with smooth stem and leaves, the stem furrowed. The flowers are small, yellow, in axillary and terminal spikes, on foot stalks; the flowers mostly inclined to one side. In drying it exhales an agreeable scent, and horses and cattle are very fond of it. We have never seen it in this vicinity, except in the northerly part of Leicester, where it grows, apparently indigenous, but may have been introduced. We recommend it to the notice of farmers, especially to those who keep dairies, and hope, that in the course of the next season, a fair trial may be made of it, believing that the cultivation of it may yet be of great advantage to our country.—*Worcester Spy.*

Easy method of making excellent red or black Cherry Wine.

Bruise twenty-four pounds of the finest ripe cherries, either red or black, first taking away the stalks and separating them from any rotten or unripe fruit. After pressing out the juice and even breaking the stones and crushing the kernels, let the whole ferment together for 12

hours. Then run the liquid through a large flannel bag, into a vessel beneath, containing a pound of fine powdered loaf or Havana sugar; forcing also, with a ladle or the hands, as much of the juice as possible from the mass. When the sugar is thoroughly dissolved, put the liquor up in bottles, filling each above half up the neck, or within nearly an inch of the cork.—This quantity of good cherries will generally make six quart bottles of a most pleasant and salubrious wine, without dregs; of a fine deep red color, more or less bright, according to the kind of cherries used; and will keep considerably well, if put in a cool place, more than a year. This wine will be fit to drink in two or three months. When the juice is first pressed out, the mass should be wrung as dry as possible in a napkin, before the stones are attempted to be broken and the kernels bruised; which being done with the mallet or otherwise, the whole is to be returned into the juice, that it may ferment together. The same rule should be observed in making all other kinds of wine from stoned fruits, where the flavor of the kernel is desirable.—*English publication.*

From the Berkshire Star of August 14.

The Crops.—All the crops fit for harvest, in this vicinity, are abundant; and although we have had, of late, much of what the farmers term *catching weather*, they have been saved in good order. The crops now upon the ground are very fine, particularly corn and potatoes, and bid fair to yield a greater product than we have had for a number of years past.

The ravages of the Hessian fly, in former years, among the wheat have discouraged many of our best farmers from attempting to cultivate this crop; but this difficulty may be easily obviated by a proper preparation of the seed before sown. The few fields of wheat grown in this town, we are told, will produce from 20 to 30 bushels to the acre. If this be the fact, (and we do not doubt it,) we hope our farmers will give more of their attention to the cultivation of this valuable crop, and thereby retain in the county many hundred dollars, which now go to a neighboring state for the purchase of flour.

Manufacturers Beware.

A lot of waste wool was discovered to be on fire at the Merino Factory, in Dudley, Mass. on Thursday the 7th inst. On removing it from the place where it had laid in a heap for a length of time, near the picker, and exposing it to the air out of door, it was all of a blaze in less than ten minutes. The Factory belongs to John Brown, & Co. who were present and saw the waste on fire. As it has never been positively known whether wool waste would take fire (by being in a heap for any length of time or not) the Co. consider it a duty to give this information to Manufacturers, who are liable every day to be exposed to fire by their waste wool. It is very probable that it would have caught the Factory on fire in less than 24 hours.

Dudley, August 12.

[*Worcester Egis.*]

Pomatum for the Lips.—Mix an ounce of the oil of bitter almonds and a little powdered cochineal; melt all together, strain it through a cloth in a little rose water, and rub the lips at night.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—With much pleasure and interest I perused an article in your paper No. 48, taken from the Massachusetts Agricultural Repository for June, 1823, on "*Steeps for seeds previous to sowing*." The writer of that article (very properly I conceive) questions their possessing any *fructifying* property, yet as he has placed little or no merit to their credit, and as I have made use of some of them for several years past to advantage, I am induced to detail some facts respecting their utility as an *antidote* rather than an *aliment*.

The present season, before planting my corn, the seed was soaked in a strong salt petre pickle (the same my hams were cured in) for about three days. I have made this my practice for several years past, as a safeguard against the attacks of the *wire worm*, which, as every farmer knows, are more deadly than any other of the worm tribe, on corn, as they sap the very foundation, by directly eating into the germ or chit of the seed. It so happened that immediately after planting, a heavy rain of twenty-four hours laid many parts of the field under water for several days. When the ground became sufficiently dry to pulverize, I prepared to replant, when to my astonishment I discovered the sprouts forcing their way through the crust now formed over them. Had not the seed been soaked in *brine*, putrefaction would have commenced before vegetation could have ensued. The last mentioned circumstance I consider of sufficient importance to urge the use of the brine, both with corn and wheat before sowing. Although the field was literally full of the *wire worm*, yet in no instance did I detect their ravages on the seed.*

My experience in the use of steeps for seed wheat before sowing, has also impressed the belief in their (lye from wood ashes or lime water) value as an antidote against the smut. Several years since I sowed my wheat with no other precaution,—the appearance of the seed being excellent—than a slight washing with water; the result at harvest, although an excellent year for wheat in Massachusetts, was, almost seven-eighths of the crop smutty; of course of no use but for very bad fodder, whilst my neighbors, who sowed the same kind of wheat, but took the precaution of liming, had fine crops.†

Since the beforementioned year, I have made use of lime or lye, and in no instance suffered by smut, except the *Nielle*, (or *blast*) of the French, which appears to be a disease taken in with the food of the plant, as the ear on bursting from its prison, exhibits a jet-black appearance, composed of a dust not very unlike that contained in the kernel of the smutty wheat.

On inspecting the roots of many of the diseased plants, I discovered in 19-20ths of their number, pieces of charcoal adhering to the *feeders*, or lateral roots. I found none at the roots of the healthy stalks. If this, on further trial, should prove to be the source of the dis-

ease, the only advantage to be derived from the discovery, will be to desist from the use of ashes, unless sifted, on our wheat lands. How far the dust blown from the blasted heads on those that are healthy, will tend to propagate the smut for the next years sowing, I shall at present leave to the investigation of persons of more leisure and ability than your humble servant,

PAYSON WILLIAMS.

Fitchburgh, August, 1823.

From the Northampton Gazette.

PEAR TREES.

During the months of June and July last, the ends of the branches of pear trees in this town were observed to turn brown and perish suddenly. Many trees are nearly ruined, others have but one or two limbs affected, and some are uninjured. The mischief has been attributed by some to lightning, blasting winds, &c. but there can be but little doubt that the cause of the injury is the insect described by Professor Peck, in the Massachusetts Agricultural Journal for January, 1817. On examining the inner part of the wood of the withered branches, a small insect has been discovered in a few limbs. More would probably have been found if the examination had been made earlier. Professor P. calls the insect which destroys the branches of the pear tree, *Scolytus Pyri*, and gives a particular description of it, with a plate. It is one-tenth of an inch long, and one twenty-fifth of an inch in diameter. It deposits its eggs between the bud and stem before the month of August is passed. After the egg is hatched the grub eats its way through the cup into the hardest part of the wood, and passes through its chrysalis state before the next summer. Professor P. says the mischievous effects of this minute insect are observed in June and July; and that the dead part of the branches should be cut off and burnt without delay, as the insects have not then left them. We are informed that the limbs of some quince trees have perished, apparently from the same cause.

FRAGRANCE OF FLOWERS.

"It has been stated that the fragrance of flowers depends upon the volatile oils they contain; and these oils, by their constant evaporation, surround the flower with a kind of odorous atmosphere; which, at the same time that it entices larger insects, may probably preserve the parts of fructification from the ravage of the smaller ones. Volatile oils, or odorous substances, seem particularly destructive to these minute insects and animalcules which feed on the substance of vegetables; thousands of aphides may be usually seen in the stalk and leaves of the rose; but none of them are ever observed on the flower. Camphor is used to preserve the collections of naturalists. The woods that contain aromatic oils are remarked for their indestructibility; and for their exemption from the attack of insects: this is particularly the case with the cedar, rose-wood and cypress. The gates of Constantinople, which were made of this last wood, stood entire from the time of Constantine, their founder, to that of Pope Eugene IV. a period of 1100 years." DAVY.

"The flour of hard wheat is generally superior to that made from soft; and there is no

difference in the process of making them into bread; but the flour from hard wheat will imbibe and retain more water in making into bread; and will consequently produce more weight of bread: it is the practice here, and which, I am persuaded, it would be advisable to adopt, to make bread with flour of hard and soft wheat, which, by being mixed, will make the bread much better." DAVY.

From the New York Statesman.

The following extract of a letter is from a very respectable gentleman residing near Trenton and if you think it merits a place in your paper, you are at liberty to publish it.

"For some years past, Col. Clark, of Philadelphia, has been engaged in preparing a boat and apparatus, and making experiments to effect a navigation against the rapids in the Delaware, opposite to this place, as a cheap substitute for locks and canals, and contrary to the prevailing opinion of our citizens, he has finally succeeded. I had the curiosity yesterday to visit the vicinity of his operations with a view to witness the passage of a Durham boat on his plan against the current, and on expressing my wish, although an entire stranger to Mr. Clark he politely took me on board, and I had the satisfaction of passing the rapids by means of his novel, ingenious, and yet simple contrivance, and also of seeing a river boat containing considerable freight towed up by it with great apparent ease. The power I have no doubt was fully competent to have taken up 10 or 15 tons additional. If such however was not the case the principles on which the apparatus are constructed and applied, admit of increasing the power to any required extent.

The machinery consists of a pair of water wheels supported by a shaft placed across the boat: there is also another short shaft; they are both furnished with a drum, over which a rope is passed by several convolutions and fastened by one end to an anchor at the head of the rapids, while the other is secured to a bug drag at their foot, and is kept constantly on a strain by the action of the current. The water wheels are turned by the running water, and when the apparatus is placed in gear, the rope winds on the drums in the ascending direction and off in the other, and occasions the boat to ascend at the rate of three miles per hour. The plan is exceeding simple, and no doubt it will be adopted on all our large rivers, and prove a great public benefit.

The channel of the Delaware at this place is very crooked, shallow and rocky; it however admits of a suitable improvement for this kind of navigation at a comparatively small expense, and the same may be said of all the rapids on this river for a considerable distance up. It should be recollected that three boatmen are necessary to take an empty boat up the Delaware, and for them it often proves a difficult undertaking:—when freight is taken up, additional hands are employed; but so little account is made of this mode of transportation, owing to the attendant difficulties, risk, and expense, that most of the supplies for the upper country are conveyed over land, either from your city or Philadelphia. Coal is taken down in boats which do not return, and which occasions a very great expense.

* The copper head I nearly extirpate by ploughing deep, just as winter is setting in, which however has little or no effect on the *wire worm*.

† The testimony of M. Tillet, M. Du Hamel, Mr. Tull, Arthur Young, and an able writer in the Massachusetts Repository for July, 1813, over the signature of Seneu, may be considered as almost conclusive on this subject.

From the Boston Daily Advertiser.

A Hydrostatic press has recently been erected in Gardiner, (Me.) for the purpose of pressing hay for market. It was constructed by Mr. Adell; and his forcing pump, which is of bell metal, was cast by Mr. Wing, both of Gardiner. Mr. K. had no other information respecting the press construction, but what was obtained from Rees' Cyclopedia. But his ingenuity has enabled him not only to construct so nice a machine, but to improve and greatly to simplify the operation and advantages of the press thus described in the Hallowell Gazette.

The size of the press when the hay is first put into it is 27 inches wide, by 42 inches, and 12 feet high. In this the hay is first trodden down by foot, as close as possible; the follower is then forced down 3 feet 3 inches by a powerful lever, moved by a double pulley, and is only secured; the piston is then raised by the forcing pump 8 feet 2 inches, which reduces the capacity of the box containing the hay to about 20 cubic feet. The hay is then bound by iron bands, made of nail rods; and is driven out of the press by a perpetual lever, worked with a coggle joint, and moved by the water-wheel. Wooden hoops, of the best quality, are tried at first for binding the hay, instead of iron bands; but they instantly broke. Only a few bundles have yet been pressed. They weighed from 613 to 851 lbs. according to the kind of hay that was used. An attempt was made to re-press one bundle in order to make it more compact, but as soon as the piston was lowered, it burst the iron bands, and provided it was pressed sufficiently for practical purposes. If pressed more it would require much stronger bands; the expense of which would more than counterbalance the advantage gained by the greater compactness of the hay. When the bundles are taken out of the press, they gradually expand and stretch the bands, so that the next day, they will measure from 23 to 25 cubic feet according to the dryness and elasticity of the hay. From several experiments it was found, that the white pine timber of this country, partly seasoned, weighs about 23½ lbs. per cubic foot. The heaviest bundle of hay when in the press weighed 42½ lbs. to the cubic foot, or 50 per cent heavier than pine timber; and when expanded, 34 lbs. to the cubic foot, or 25 per cent heavier than pine timber. A safety valve has yet been loaded, so as to give purchase of 225 tons, which is not one third of the power of the press. It is therefore apparent how much closer hay might be pressed, if it would pay the additional expense. The expense of the press, including the barn in which it is placed, has exceeded \$3,000. The quantity of which great quantities were necessary to enable the press to resist the enormous pressure forms the principal item in the expense. In a country, so peculiarly favourable to the raising of grass, hay must become a great article of export, when it can be compressed, so as to be safely transported, without the necessity of using ballast; and when it is not liable to be injured from exposure to the weather. Some persons have supposed, that the exportation of hay would injure the country, by depriving it of manure, which would have been made, had the hay been consumed at home; but the farmer is more likely to injure his farm by raising and selling grain as hay; and when he finds a good

and certain market for an article so easily raised as hay, he will be induced to use plaster and other artificial manures, by which he may certainly double his crop; and while therefore he sells a portion of his crop, he will still retain more to be consumed on his farm, than he would have had but for the stimulus given to his exertion by the foreign demand."

From the American Farmer.

DYSPEPSIA.

MR. SKINNER—I observe in number 12, of your 5th vol. "A Constant Reader" requests that you will inquire of some of your many correspondents, and publish in the American Farmer, directions for the treatment and cure of Dyspepsia." Having seen no reply to the request, I am induced to offer the result of my own experience; without entering into any investigation of the cause of this fashionable disease either remote or proximate. A rigid attention to diet, both as to quantity and quality is indispensable; I do not mean that sort of abstinence where the patient eats small quantities at a time, but by eating frequently, consumes more than people usually do who only eat at the ordinary and regular meals: beef, mutton or chicken, roasted or boiled, will be found as innocent, perhaps as any other food. High seasoned dishes should be particularly avoided, as being not only pernicious in themselves, but by provoking the appetite to take more than sufficient; and for this last reason, spirits, wine, or strong beer should not be indulged in until after eating, and then sparingly. Coffee was found to disagree with my stomach, being generally thrown up by eructation soon after drinking it in the morning, if exercise was used immediately after. Tea and milk produced nearly the same result; which led me to seek for a succedaneum; some warm beverage having become by habit, not only comfortable, but almost a necessary. Accident led me several years past, when riding, to chew the leaves, and sometimes the buds of the sassafras to allay the intolerable heat and pain produced by the highly concentrated acid on the stomach; the effect of which caused me to think of sassafras tea, which, in a few weeks, produced the most happy effect; the symptoms having been entirely removed, and no return having been as yet experienced, although five months have passed over. There are two species of sassafras, the one having a red, the other a white root—the white is much the most pleasant, and should not be made very strong. Sugar and cream may be used as with other tea. A little experience will teach the most agreeable method of preparing it. Candor induces me to mention a fact in my own case, which possibly, may cause medical gentlemen to doubt the efficacy of my nostrum. About six or eight weeks after commencing the use of the sassafras tea, the first joint of the great toe on my right foot was for the first time inflamed, and very painful for three or four days; and in a day or two after that, the outside of my left foot was so tender as to prevent me from bearing my weight on it. I should, myself, have believed that those attacks in the feet had produced the relief to the stomach, if that viscus had not been relieved, two weeks previously. More might be added, but you will, no doubt, think that I have already trespassed sufficiently. If you think these observations worthy of a

place in your paper, you are at liberty to publish them—without, however, giving my name, unless you may think proper to give it to a "Constant Reader."

From the New England Galaxy.

PREVENTION OF CONTAGIOUS FEVERS.

It has often been remarked, in my hearing, that physicians, seldom, if ever, caught fevers from their patients, however sick they might be, or however filthy the places might be in which they resided. The reasons offered for the physicians thus escaping, are, that they know what to take as a prevention of this specific contagion, or infection. This is a very serious charge against the faculty, and rather inconsistent, for if any one of them could certainly know of any certain method of preventing the contagion or infection of fevers, by publishing the same, he would be sure of an independent fortune.

The following rules as stated by the celebrated Doctor John Haygarth are the best, and in fact, the only ones, at present known, for the prevention of contagious fevers, and several other disorders.

The Doctor says, "It may be proper previously to observe, that an infectious fever, in a small, close, and dirty room, is caught by a very great proportion of mankind; not less than by twenty-two out of twenty-three, or a still higher proportion; but in a large, airy, clean apartment, even putrid fevers are seldom or never infections. Where the poisonous vapour is much diluted with fresh air, it is not noxious. From a large collection, and an attentive consideration of facts relative to this distemper, have been formed the following Rules.

1st. As safety from danger entirely depends on cleanliness and fresh air, the room-door of a patient ill of an infectious fever, especially in the habitations of the poor, should never be shut; a window in it during the day ought to be frequently opened. In bad cases, a current of air, between a window and door both wide open, may be proper: if the air be very cold or damp, the curtains* of the patient's bed may be drawn close during this ventilation, should peculiar circumstances require such caution. These regulations would be highly useful, both to the patient and nurses; but are particularly important previous to the arrival of any visitor.

2. The bed-curtains should never be drawn round the patient, but only on the side next the light, so as to shade the face; except while there is a current of air between a window and door.

3. Dirty clothes, utensils, &c. should be frequently changed, immediately immersed in cold water, and washed clean.

4. All discharges from the patient should be instantly removed. The floor near the patient's bed should be rubbed clean every day with a mop, or cloth wet with cold vinegar and water.

5. The air in a sick room has a more infectious quality in some parts than in others. Visitors and attendants should avoid the current of the patient's breath; the air which ascends from his body, especially if the bed-curtains be closed, and the vapor arising from all evacuations. When medical or other duties require a visi-

* Curtains never ought to be allowed to any bed, occupied by any person, whether sick or well.

ter to be placed in these situations of danger, infection may be frequently prevented by a temporary suspension of breath, or respiration.

6. Visitors should not go into an infectious chamber with an empty stomach; and, in doubtful circumstances, on coming out, they should blow from the nose, and spit from the mouth any infectious poison, which may have been drawn in by the breath, and may adhere to those passages.

7. Paupers from jails and other infected places ought not to be brought before magistrates without clean hands, face, and hair, and in their sundry clothes. There is considerable danger of infection by the near approach of people covered with contagious dirt in a close and small room."

Remark.—These rules of prevention will preserve all the neighbors from contagious fever, and, in most cases, the remainder of the family, after one of them has been attacked.

They will enable medical, clerical, and other visitors to perform their important duties with safety to themselves.

It may, with propriety, be added, that frequent washing of the body in cold water, either salt or fresh, during the warm season, is another powerful preventive of contagious diseases, and productive of general good health and comfort.

The Doctor remarks, that by these rules of prevention, Chester has been preserved from Typhus for thirty-six years.

At Manchester, the number of patients ill of fever during twenty-four months in 1793 and 1796, was 1056. By the establishment of a house of recovery, and by observing these rules of prevention, in two months the number of patients was reduced to 25.

The annual number of deaths by fever in London during the last century was 3188. But by thoroughly cleansing from contagious dirt, the houses of patients admitted into fever hospitals established in 1802, and by strictly observing these rules of prevention, the annual deaths in the metropolis were gradually reduced, and in 1811 were only 906. These facts are recorded by the Bishop of Durham, Mr. Vansittart, and Sir Thomas Bernard.

The typhous contagion remains in the body in a latent state from about the 10th to the 72d day, reckoning between the time of exposure to the poison and the commencement of the fever.—This law of Nature was discovered by Dr. H. in 1781, from observations on 72 cases. It was fully confirmed by Dr. Bancroft, in 1809, from observations on 99 cases. He observed that the latent period of typhus varied from the 13th to the 68th day. Hence it is manifest that an infected person may travel, in perfect health, from and to the remotest parts of Ireland and Britain.

CURE FOR THE GOUT.

A gouty gentleman who has resided in the south of France for some years, informs us that he has remained free from gout four years, in consequence of wearing oiled stockings over fine worsted ones, day and night. Previously to their use he had been subjected to a paroxysm every six months. This practice, he says, is common in the south of France, and throughout Italy.—*London paper.*

NEW ENGLAND FARMER.

SATURDAY, AUGUST 23, 1823.

Extracts from a work lately published by WILLIAM COBBETT, entitled "*Coltage Economy*," with occasional remarks on some of the statements of the author.

This work of 207 pages, small 12 mo. was published in London in 1822. It contains "Information relative to the brewing of Beer, making of Bread, keeping of Cows, Pigs, Bees, Ewes, Goats, Poultry and Rabbits, and relative to other matters deemed useful in the conducting of the affairs of a Laborer's Family." Although it is more especially calculated for the use of the laboring classes of Great Britain, it presents us many things which may be highly useful to all classes in all countries. It is tinctured with some of Mr. Cobbett's peculiarities and prejudices of a moral, religious and political nature; which circumstance, together with that of a considerable part of the book's not being adapted to our government, climate, manners, and state of society, will, probably, prevent its being republished in this country. We wish, however, to put our readers in possession of many excellent things which it contains, as well as to convey the opinions of other writers on some of the same topics, together with some facts and observations which oppose and others which corroborate Mr. Cobbett's assertions and reasonings.

In the introduction to the work, we have the following strong sentiments, expressed in a style all nerve and intellect.

"The word *Economy*, like a great many others, has, in its application, been very much abused. It is generally used as if it meant parsimony, stinginess, or niggardiness; and, at best, merely the refraining from expending money. Hence misers and close-fisted men disguise their propensity and conduct under the name of *Economy*; whereas the most liberal disposition, a disposition precisely the contrary of that of the miser, is perfectly consistent with economy.

"*Economy* means, *management*, and nothing more; and it is generally applied to the affairs of a house and family, which affairs are an object of the greatest importance, whether as relating to individuals or to a nation. A nation is made powerful and honoured in the world not so much by the number of its people as by the ability and character of that people; and the ability and character of a people depend, in a great measure, upon the *economy* of the several families which, all taken together, make up the nation. There never yet was, and never will be, a nation *permanently great*, consisting, for the greater part, of wretched and miserable families.

"In every view of the matter, therefore, it is desirable, that the families of which a nation consists should be happily off; and, as this depends, in a great degree, upon the *management* of their concerns, the present work is intended to convey to the families of the *Labouring classes* in particular, such information as I think may be useful with regard to that management.

"I lay it down as a maxim, that, for a family to be happy, they must be well supplied with *food and raiment*. It is a sorry effort the people make to persuade others, or to persuade themselves, that they can be happy in a state of *want* of the necessities of life. The doctrines, which fanaticism preaches, and which teach men to be content with *poverty*, have, very pernicious tendency, and are calculated to favor tyrants by giving them passive slaves. To live well, to enjoy all things that make life pleasant, is the right of every man who constantly uses his strength judiciously and lawfully. In spite the man that is *poor and contented*; for such content is a certain proof of a base disposition, a disposition which is the enemy of industry, all exertion, all love of independence.

"Let it be understood, however, that *poverty* I mean *real want*, a real insufficiency in the food and raiment and lodging necessary to health and decency; and not that imaginary poverty of which some persons complain. A man, who, by his own and his family's labor can provide a sufficiency of food and raiment and a comfortable dwelling place, is not a *poor man*. There must be different ranks and degrees in every civil society, and, indeed, so is even amongst the savage tribes. There must be different degrees of wealth; some must have more than others; and the richest must be a great deal richer than the least rich. But it is necessary to the very existence of a people, that nine out of ten should live wholly in the sweat of their brow; and, is it not degrading to human nature, that all the nine tenths should be called *poor*; and, what is still worse call themselves *poor*, and be *contented* in that degraded state?"

There is much good sense in these remarks. We may add that there can be no real rational freedom enjoyed by a man who is *poor*, in Mr. Cobbett's sense of the word. Such a man is slave to his creditors, a slave to his circumstances; the elements tyrannize over him. A man may be a citizen of a free government, but cannot be a *freeman*, while under the dominion of *want*, the most cruel of masters.

(TO BE CONTINUED.)

CURRENT WINE.

We learn that the Messrs. Kenricks, near Brighton, have manufactured about 1700 gallons of Current Wine the present season. From the general approbation expressed by skillful connoisseurs, they indulge a hope of having brought the manufacture of this article to so great perfection, as not only to be admired, but entitled to a decided preference over much of the foreign wine in general use.

Mr. Murdock, Grocer, in Dock Square, will show samples of this Wine, or Columbian Grapeseille, sufficiently matured by age, and well refined, and supply any quantity that may be wanted, by the quarter-cask, demijohn, or single gallon, on moderate terms.

The duties paid by the Auctioneers in this city, under the late law of the Commonwealth for the quarter ending July 31st, amounted to \$7187 99.

COMMUNICATION.

Admiral Sir Isaac Coffin, member of the British Parliament, leaving from a regard to his native State, with a wish to promote its Agriculture, purchased at great expense, a Bull of the first breed in Great Britain, and sent him as a present to the Trustees of the Massachusetts Society for promoting Agriculture—a meeting of the Trustees held this 21st day of August, 1833:

That the thanks of this Board be presented to the Corresponding Secretary to Admiral Coffin, for his very valuable present, and that he express to his sense of his patriotism, and attachment to native soil, which neither time nor distance had been competent to weaken.

That the animal presented by him, is a noble one, affords in his own person, proof of his descent from most approved stocks, independent of the historical pedigree which accompanies him.

That for the present season, he be placed at the farm John Prince, Esq. of Roxbury, and that he will be entitled to be used by any farmers at the moderate rate of five dollars for each cow. In future years he be removed, from time to time, to various parts of the Commonwealth, at the discretion of the Trustees, and in no case shall an higher premium be offered than is above stated, it being the wish of this Board to improve the stock of the country as rapidly as possible; and as the Trustees receive no emolument from him, should there be any, it will go to support great interest of Agriculture. If a lower sum should be offered, farmers might be careless of his progeny; higher, they might not choose to incur so great expense, at so much risk; his cost in England, was \$61; the expenses of his transportation, &c. \$113, cents; whole amount \$694 90. His pedigree, as was got by Mr. Wetherell's North Star; dam by et; grandam by Wellington; great grandam by ety.

North Star was by Comet; dam by Baronet; grand by Cripple; g. grandam by Irishman; g. g. grand by Hubback.

Notice will be given seasonably, every spring, in this county, and town, this Bull will be placed, to the intent of affording to all parts of the State the advantages which may be derived from a Stock, which the agriculturists of Europe have deemed the most perfect, in regard to disposition for fattening, and aptitude for the dairy. This improved breed is not the result of accident, but of great care, and attention, to such crosses of the breed of horned cattle as would combine the most valuable qualities. The Trustees have every reason to believe, that the Bull sent by Admiral Coffin, (which arrived in due season) combines all these qualities, judging from his appearance and appearance.

When the Trustees speak of the price of five dollars each cow, being moderate, they have no reference to ordinary prices, but to the value affixed to bulls of approved race, in England and America. Bulls of six months old, have been sold as high as 50 dollars, or \$233, in England, and in this country, at 100 dollars. If the price were diminished, the best would not be sent to the animal, and it is the duty of the Trustees that only the best cows should be sent. Breeds of cattle can never be improved, unless there be sufficient encouragement offered for their selection, and high prices alone can effect this desideratum.

Admiral Coffin was elected an Honorary Member of the Society, and a vote passed to present him the Society's Gold Medal, and the numbers of their Journal.

A copy from the record,
BENJ. GUILD, Asst. Rec. Secretary.

FOREIGN.

The last advices from Paris are to July 2. By these it would seem that the French are proceeding in a triumphant manner to settle the political concerns of the world in such a mode as best comports with the highest interests of the victors. The hand of opposition is weak and paralalytic, and is hardly elevated against the Gallic conquerors, who now perform pretty nearly their duty with pleasure throughout a country whose inhabitants can no more turn freedom to a good account than

could a stupid animal of some ferocious species, that had been accustomed to a cage. The marches of the invaders appear more like peaceful processions than military movements in a hostile country. Instead of fighting battles, they are pursuing fugitives, and they tell us they are almost every where welcomed with enthusiasm by the great mass of the Spanish population.

It is said, in one of their despatches, that "Cadiz, as well as the island of Leon, are destitute of subsistence; that the greatest confusion prevails among the wrecks of the revolutionary army, which have fled thither, to the number of 7000 or 8000 men; and that they have not prepared any means of defence." Seville made some resistance, but was laid under a heavy contribution. At Alcala was some fighting, but the fight soon became a chase, in which the French were the winners, for they say "several hundred soldiers were taken in the retreat, and many presented themselves as deserters." If we make all possible allowances for certain figures of rhetoric, usually abounding in French Bulletins, called hyperboles, alias gasconades, it is impossible not to conclude that Spanish liberty is suspended for a season, if not absolutely expatriated, or annihilated.

The Regency at Madrid, got up under French auspices, has issued a decree for sequestering the property of the Cortes, together with the members of the regency of Seville, and others who have rendered themselves obnoxious to the party now dominant. They proclaim that the members of the Cortes, who have adhered to the dethronement of the King, shall, for that act alone, be declared guilty of high treason, and the punishment adjudged by the law on those guilty of this crime shall be inflicted on them by the Courts of law on the simple recognition of their identity.

The Greeks have established a General Government for the whole nation. The first meeting of their National Congress, under the new constitution, closed on the 30th of April last. The thanks of that Congress have been voted to the armies through whose valor, in the course of sixteen months, more than 90,000 of their enemies had been destroyed. The High Admiral of the Turkish fleet had been ordered to commence the immediate attack of the Grecian Islands, and to prosecute the war with the utmost vigor. The same orders had been issued to the Pachas in Thessaly, Livadia, &c. and accounts from Larissa to the 2d May stated, that the Pacha of Scutoria had embodied 30,000 men, and that columns were traversing that quarter. On the other hand, it is said that the Greeks are making great preparations to repel the enemy—they are fully aware of the dangers which menace them, but notwithstanding, are full of energy and confidence.

DOMESTIC.

Public sale of Lands.—The President has issued a proclamation for a public sale of lands at New Orleans on the first Monday of February next. These lands are situated southwest from the city of New Orleans, and lie on the Delta, from three to ten and twelve feet above high-water mark. There are above 1500 lots, containing for the most part 160 acres each, and having generally a front of four acres on the water with a depth of forty acres. They are well adapted for sugar plantations.

Fire.—The Virginia State Penitentiary was destroyed by fire on the 9th inst. It is supposed that the fire commenced in a shoe maker's shop, where sometimes 20 or 25 worked at once. It is suspected that the fire was the work of design. There were 244 convicts in the building, all of whom were saved. Loss to the Commonwealth supposed to be \$200,000.

Daring Robbery.—The rooms of a number of the boarders at Mr. Bunker's Mansion House, Broadway, New York, were lately entered between 1 and 5 o'clock, in the morning, by some villain unknown, and robbed of cash and other property to a large amount.

Hail Storm.—On the 4th inst. a destructive storm of hail visited Quakertown, in Penn. For the width of three miles were to be seen hailstones several hours after the storm had abated; some of which measured 7-12 and 8 inches in circumference. Fences were prostrated, trees torn up by the roots, promising crops

of Indian corn and buck-wheat were cut to pieces by the hail, and blown in every direction. In that village alone upwards of 1500 panes of glass were broken, and much other serious damage sustained in that place and its neighborhood.

Extraordinary Hailstone.—The Hartford Mirror says that a hailstone, or rather mass of ice fell during a thunder storm, in the presence of several persons, in Moulton, Mass. of the following very extraordinary dimensions: 1 Extremes 4 ft. long, 3 do. wide, 2 do. thick. The appearance is said to have been that of a compact body of hail stones, as firmly united as hail usually is. After removing the rough parts of the body there remained a solid block 2 feet 3 inches long, 1 foot 6 inches wide, and 1 foot 3 inches thick.

One Johnson (reported to be the famous "Thunder-bolt," the companion and tutor of Martin) has been pursued from Portland to Canada, and arrested for running away with a horse and chaise, and been safely caged in Portland. He is represented as a powerful man; has exhibited the marks which Martin says he had on him; and is said to have cleared himself from four or five of his pursuers, but found a match in a brother Liberatorian, who knocked up his career by knocking him down.—Continued.

ANECDOTES.—Selected from Thacher's Journal.

When the Count D'Estaing's fleet appeared near the British batteries, in the harbor of Rhode Island, a severe cannonade was commenced, and several shot passed through the houses in town, and occasioned great consternation among the inhabitants. A shot passed through the door of Mrs. Mason's house, just above the floor. The family were alarmed, not knowing where to flee for safety. A negro man ran and sat himself down very composedly, with his back against the shot hole in the door, and being asked by young Mr. Mason why he chose that situation, he replied, "Massa, you never know two bullet go in one place."

A criminal was executed who had been guilty of forging a number of discharges, by which he and more than a hundred soldiers had left the army. He appeared to be penitent, and behaved with uncommon fortitude and resolution. He addressed the soldiers, desired them to be faithful to their country and obedient to their officers, and advised the officers to be punctual in all their engagements to the soldiers, and give them no cause to desert. He examined the halter, and told the hangman the knot was not made right, and that the rope was not strong enough, as he was a heavy man. Having adjusted the knot and fixed it round his neck, he was swung off instantly. The rope broke, and he fell to the ground, by which he was very much bruised. He calmly reascended the ladder and said, "I told you the rope was not strong enough, do get a stronger one." Another being procured, he was launched into eternity.

At an attack on Charleston, Sir Peter Parker, Commodore in the British fleet, had a material part of his breeches torn away, and was otherwise wounded. In a southern newspaper were inserted the following lines on Sir Peter's disaster:

"If honor in the breech is lodg'd,
As Hudibras hath shown,
It may from hence be fairly judg'd
Sir Peter's honor's gone."

We were invited to visit a curiosity. This is a monster in the human form. He is twenty-seven years of age, his face from the upper part of his forehead to the end of his chin, measures twenty inches, his eyes and nose are remarkably large and prominent, chin large and pointed. His features are coarse, irregular and disgusting, and his voice is rough and sonorous. His body is only twenty-seven inches in length, his limbs are small, and much deformed, and he has the use of one hand only. He has never been able to stand, or sit up, as he cannot support the enormous weight of his head; but lies constantly in a large cradle, with his head supported on pillows. He is visited by great numbers of people, and is peculiarly fond of the company of clergymen, always inquiring for them among his visitors, and taking great pleasure in receiving religious instruction. General Washington made him a visit, and asked, "whether he was a whig or tory?" He replied, that he had never taken an active part on either side."

WAR HORSES.

At the battle of Germantown, General Wayne rode his gallant roan, and in charging the en-

emy, his horse received a wound in his head, and fell, as was supposed, dead. Two days after, the roan returned to the American camp, not materially injured, and was again fit for service.

During the battle of Waterloo, some of the horses, as they lay on the ground, having recovered from the first agony of their wounds, fell to eating the grass about them, thus surrounding themselves with a circle of bare ground, the limited extent of which, showed their weakness; others of these interesting animals were observed quietly grazing in the middle of the field, between the two hostile lines, their riders having been shot off their backs; and the balls that flew over their heads, and the roaring behind and before, caused no respite of the usual instinct of their nature.—When a charge of cavalry went past, near to any of these stray horses, the trained animals would set off, form themselves in the rear of their mounted companions, and though without riders, gallop strenuously along with the rest, not stopping or flinching when the fatal shock with the enemy took place.

The Address of the Hon. Dewitt Clinton, recently delivered before a literary Society at Schenectady, New York, is warmly commended in the New York papers, as a choice specimen of learning, eloquence and patriotism. Mr. C. closed his address with the following noble and eloquent peroration:—

"Finally, whatever may be our thoughts, our words, our writings, or our actions, let them all be subservient to the promotion of science and the prosperity of our country. Pleasure is a shadow, wealth is vanity, and power a pageant—but knowledge is extatic in enjoyment, perennial in fame, unlimited in space and infinite in duration. In the performance of its sacred offices, it fears no danger, spares no expense, omits no exertion. It scales the mountains, looks into the volcano, dives into the ocean, perforates the earth, wings its flight into the skies, encircles the globe, explores sea and land, contemplates the distant, examines the minute, comprehends the great, and ascends to the sublime. No place too remote for its grasp—no heavens too exalted for its reach. "His seat is the bosom of God, his voice the harmony of the world. All things in heaven and earth do it homage, the very least as feeling its care and the greatest as not exempt from its power. Both angels and men, creatures, of what condition soever, though each in different sort and manner, yet all with uniform consent admiring it as the parent of peace and happiness."

An Innholder a successful preacher.

Mr. A— was a speculator in lands, and sold a farm to Mr. B—, who was an active industrious young man, but in the habit of making too free use of ardent spirits. He settled upon the land and was much engaged in getting out lumber to pay for it. While on his way with his team from the lot to the wharf, he would never forget to stop at Mr. C's tavern, and take what he would call a good drink of grog. The habit of excessive drinking grew upon him until he was frequently seen intoxicated. At length Mr. A— had occasion to call at the same inn. The landlord observed to him B. will never pay you for your land; he

is growing very intemperate. I know that said Mr. A. but he is a good fellow to work, when he has cleared up land, and made all betterments he can, I mean to take the farm back again. Soon after this B. came in as usual for his grog. The Innholder related the conversation, which had passed between him and Mr. A. This proved a powerful sermon. B. listened with attention, received the mug with trembling hand, and said, this is the last sp I will ever drink. He has reformed, paid his debts, and is now living in the rational enjoyment of the good things of this life and in the bosom of a happy family. Ye, who are laboring hard to pay for your land, be entreated learn from this incident an important lesson of instruction.

English Fogs.—The fogs of England have at all times been the complaint of foreigners. Gondomar, the Spanish Ambassador, when some one was going to Spain, waited on him to ask whether he had any commands, replied "Only my compliments to the Sun, who have not been seen since I came to England." Caccioli, the Neapolitan minister to the English Court, used to say that the only ripe fruit had seen in England, were roasted apples, in conversation with George II. he took liberty of preferring the Moon of Naples, to the Sun of England.

A Windsor chair manufacturer of New York a few days since received a letter from an acquaintance residing in the interior (an eccentric kind of a gentleman, perhaps not actually Johnson in literature) who among other corrections of dialect, had imbibed that of pronouncing the word chair as if written with double e cheer. The old gentleman's daughter was the bearer of this epistle, which informed his friend of her recent marriage, on which occasion he called on him "for twelve cheers." The receiver of the letter perused it attentively and was not a little surprised that his friend should request so rough and boisterous a felicitation, on so tender and delicate a theme. Knowing his correspondent's eccentricity, he thought it best to humor his whim, and accordingly saluted the astonished lady with a dozen huzzas, with such tremendous vociferation, that she shrieked with terror, fled from the scene, and has not since been heard of.

An elegant writer has said, "that the period of our courtship is the happiest of our lives. If this position be true, it is impossible not to admire the prudence of a couple lately married who protracted this period of felicity for years. That they should at last think it necessary to unite in the bands of wedlock, is a strong proof that all human felicity must so or time or other have an end.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrearages are paid.

Agents who procure seven subscribers, and become responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

ON THE CULTIVATION OF WHEAT.

To raise good wheat is considered both in Africa and Europe as an object of prime consequence to the cultivator, and agricultural writers have of course been very voluminous on the subject. We shall select and condense some of their remarks, which appear to us of the greatest importance, and add what our own observation and experience has suggested.

Wheat is thought to be the most useful of farinaceous plants, and as the bounty of providence has generally decreed that those grains which are most useful shall be most common, wheat accordingly will grow in almost any part of the globe. It thrives not only temperate, but in very hot, and in very cold countries; in Africa and Siberia, as well as in the United States and Great Britain. It requires a light loamy soil, not too light, nor too heavy.

Members of the New York Board of Agriculture, volume ii, page 23, state that "wheat is best on land which contains just as much as can be combined with it without subduing the wheat to be frozen out." And the author of that article, Mr. Amos Eaton, observes that it is the clay which absorbs and retains the water injurious in wheat soils, and that a rule for the consideration of farmers, deduced from that principle, and confirmed by all observations I have been enabled to make.

"Wash a little of the soil in a tumbler of water, and observe the time required for it to become clear. If the time required exceeds six hours, it may be considered as liable to be injured by frost." W. Van Dusen, a farmer in Seneca county, N. Y. says, "that if wheat sown the last week in August, on clay soil, will generally resist the effect of frost in the autumn, and of insects in the spring." "A clay soil, according to the same work, 'having absorbed a large proportion of water, becomes harder as the water freezes, or rises up in vapour protuberances, so that the roots of the plant become disengaged from their hold on the soil. It is very manifest that if wheat be sown so early that each plant may have time to send its roots into the soil, its chance for holding its hold will be better.' We believe that, not only clay, but lime, chalk, marl, or calcareous substance is necessary to bring wheat to perfection, and the grounds of our belief shall exhibit hereafter.

Complete Farmer says, that "the best time for sowing wheat is about the beginning of September. But if the earth be very dry, it is better to defer till some shower has moistened the soil. Mr. Mortimer says that the best known wheat to be so musty and spoiling long in the ground before rain that it never came up at all. To which it is said that he has seen very good crops of wheat from seeds sown in July." We should not, however, that it would be necessary to sow wheat, sown so early, in order to get it going to seed the first year, or get it so far advanced in its growth to resist the

frosts of the succeeding winter. Sowing in dry ground is generally recommended for seeds; but wheat, being liable to be smutty, is commonly prepared by steeping in brine or lime, and in consequence of the steep, vegetation commences, and if the seed in this state is placed in earth, which is, and continues for any time dry, vegetation is checked by the drought, which kills, or greatly injures the seed.

Early sowing requires less seed than late, because the plants have more time, and are more apt to spread, and throw out a good number of stalks. More seed is required for poor than for rich lands, and rich land early sowed requires the least of any. Bordley's Husbandry says "the climate and soil of America may be believed to differ greatly from those of England, respecting the growth of some particular plants. Wheat sown there two to three bushels on an acre, yields great crops. Two bushels on an acre sown in Maryland or Pennsylvania, would yield straw without grain. In Maryland three pecks are commonly sown. I never had better crops than from half a bushel of seed wheat to an acre, in a few instances. In these instances the ground was perfectly clean and fine, after many ploughings or horse-hoings of maize, [Indian corn,] on which the wheat was sown in September, whilst the maize was ripening. It was a clay loam highly pulverized. But because of the loss of plants at other times, I preferred to sow three pecks an acre." "Grain, which is thin sown, says the Complete Farmer, is less apt to lodge. Every one must have observed that in places where foot paths are made through wheat fields, by the side of the paths, where the corn is thin, and has been trodden down in winter and spring, the plants have stood erect, when most of the corn in the same field has been laid flat on the ground, an advantage proceeding from the circumstance of the stalks having more room."

The Farmer's Assistant asserts that "the time for sowing wheat probably depends much on previous habit. Thus if it were sown a number of successive years by the middle of August, and then the time of sowing were changed at once, to October, the crop would probably be much lighter on that account; yet, where wheat has become habituated to be sown late, it will do tolerably well. The later it is sown, however, the more seed is requisite. When early sown, a bushel to the acre is believed to be sufficient; but when sown later, a bushel and an half, or more, may be necessary." The estimate of seed, however, should be formed not so much from the capacity of any particular measure, as from the number of grains, which that measure contains. The larger and fuller the seed is, the greater quantity by measure will be required; the smaller, the less quantity. Much, therefore, must be left to the discretion of the farmer, who must take into consideration the time of sowing, the quality and preparation of the soil, as well as the plumpness or the shrivelled state of the seed wheat.

If naked summer fallows are used at all they may as well be made preparatory to a crop of wheat. It may sometimes be expedient to sus-

pend, for one season, the raising of crops of any sort on land which is exhausted or greatly infested with weeds; and during the summer and autumn plough and harrow it several times, and thus thoroughly subdue it. When such a process is adopted, wheat is generally the succeeding crop. The custom of naked fallowing however, is not much approved of in modern husbandry, and that mode of preparing for wheat is rarely adopted by scientific cultivators. Sir John Sinclair says, "the raising clean, smothering, green crops, and feeding stock with them upon the land, is not only much more profitable, as far as relates to the value of the crop substituted in lieu of a fallow, but is also a more effectual method of procuring large crops of wheat, or any other crop, which may succeed the green crop." There is a disadvantage sometimes attending fallows, which we apprehend may be more detrimental in our climate than in that of Great Britain. Land which is kept in a light and pulverized state, is liable to be washed away by violent rains, and the showers of our summer season are usually more plentiful, and fall with more impetuosity than those of England, although the mean moisture is less, and there is less rain falls in the course of the year on this than the other side of the Atlantic.

In modern tillage wheat more usually follows clover than any other crop; and Bordley's Husbandry says "clover is the best preparative for a crop of wheat." In such case, English farmers, and indeed all others who *work it right*, give but one ploughing, and harrow in the seed by passing the harrow twice in a place the same way with the furrows. Mr. Bordley directs that the operations of ploughing, harrowing and sowing should immediately follow each other. Mr. Macro, an eminent English farmer says, "from upwards of twenty years experience I am of opinion, that the best way of sowing clover lands with wheat is to plough the land 10 or 14 days before you sow it, that the land may have time to get dry, and after rain to make it dress well. I am at a loss to account for the wheat thriving better on lands which have been ploughed sometime, than it does on fresh ploughed lands, which dress as well or better, but I have often tried both ways on the same lands, and always found the former answer best." Mr. Bordley in attempting to account for this effect says, "I conjecture that the clover plants being buried and the wheat sown at the same time, they both ferment and run into heat in the same period: the germ then shoots and the root is extremely delicate and tender for some days; during which the buried herbage obtains its highest degree of heat; which added to the internal heat of the germ, may, though only slightly, check and a little injure the delicate shoots of the wheat.—In sprouting barley for making malt, a little excess of heat in the bed checks, and a little more totally stops the sprouting or growth of the roots. Both modes give crops superior to what are produced on fallow. Farmers may well try both methods for determining which to prefer; that is, as well immediate sowing, on ploughing in the clover, as the method of sowing out till

10 or 14 days after having ploughed in the clover; suppose an half each way."

We believe that wheat would flourish better if it were buried deeper than it generally is in broad-cast sowing. Our opinion is founded on the following facts relating to the physiology of the wheat plant. "A grain of wheat, when put into the ground at the depth of three inches, undergoes the following transformations: As soon as the farinaceous matter which envelopes the frame of the young plant contained within it is softened into a milky state, a germ is pushed out, and at the bottom of that germ small roots soon follow. The roots are gathering strength, whilst the germ, by the aid of the milky fluid is shooting upwards; and when the milky is exhausted, the roots are in activity, and are collecting nourishment for the plant from the soil itself. This is analogous to the weaning of the young of animals, which are not abandoned by the mother till they can provide for themselves; but the care of nature does not end here; when the germ has fairly got above the surface, and become a plant, a set of upper roots are thrown out, close to the surface of the ground, which search all the superficial parts of the soil with the same activity as the under roots search the lower parts; and that part of the germ which separates the two sets of roots is now become a channel, through which the lower roots supply the plant with the nourishment they have collected. What an admirable contrivance to secure the prosperity of the plant! Two distinct sets of roots serve, in the first place, to fix the plant firmly in the ground, and to collect nourishment from every quarter. The upper roots are oppositely situated, to receive all the nourishment that comes naturally from the atmosphere, or artificially as manure to the surface; and serve the further purpose of being the base of new stems, which are tillered up, and so greatly increase the productivity of the plant. The excellence of the drill system in grain, may be probably perceived in this explanation; for in broad cast sowing, the seeds lay very near to the surface, and in this situation it is not only more exposed to accidents arising from birds, insects and the weather, but the two sets of roots are necessarily crowded together, so as almost to become indistinct; the plant is less firm, and has fewer purveyors collecting food for it."

Dr. Deane observed, that "wheat that is sowed in autumn, a clover ley excepted, should, instead of harrowing, be covered with a shallow furrow, and the surface left rough. It will be less in danger of being killed by the frost in winter, and less injured by drying winds in the following spring. The furrows should be left without harrowing; for the more uneven the ground is, the more the soil will be pulverized and mellowed by the frost." But if the crop which succeeds the wheat crop should require a smooth bottom, the land, after sowing, must be harrowed and should be rolled. Some husbandmen advise, when wheat is sown on a clover ley, to plough in the clover with a deep furrow, then plough in the seed wheat with a shallow furrow, and if the next crop in the rotation requires a level bottom, it will be necessary to harrow and roll the field as smooth as possible, after having ploughed in the seed.

[BY THE EDITOR.]

Discourses on Cold and Warm Bathing; with remarks on the effects of drinking Cold Water in Warm Weather. By JOHN G. COFFIN, M. D.

A useful Treatise with the above title has been for some time before the public, and has, we believe, met with attention in some degree corresponding to its merits. What induces us to suppose that this little work has not been permitted to pass without notice from the reading and reflecting part of the public, is the circumstance that many of its maxims have from time to time appeared in our newspapers, sometimes with, but often without acknowledging the source from whence they were derived. We think it a tract which ought to be in the possession of every family, and to be consulted, and its precepts attended to by every individual who wishes to enjoy the choicest of heaven's blessings, a sound mind in a sound body.

It is true that bathing is not quite so indispensable to animal existence as breathing, but it is hardly less so to the enjoyment of existence. If the pores of the skin are clogged, and, as it were, hermetically sealed by a coating of perspirable, and other noisome matter, life can be but little better than a long disease; and if a person thus encumbered exhibits any symptoms of cheerfulness they must be either affected or artificial, produced by unnatural effort, or the stimulus of strong drink. Thus you will find that slovens are always moody and melancholy. Long beards, long faces, dirty linen, and a sordid skin, are not only the effects, but often the causes of listlessness, gloom and stupidity. The ancients were well acquainted with these facts, and when they wished to cherish distress, and were suffering under the infliction of some calamity, which they thought rendered it a duty to "refuse to be comforted," they clothed themselves in sackcloth and ashes, and made uncleanness auxiliary to the melancholy which they considered as most befitting the most lamentable occasions. It is true that those who use a great deal of exercise in the open air, and who wash themselves with the dews of their own perspiration, stand in less need of habitual bathing than those who lead sedentary lives.

"Behold the laborer of the glebe, who toils
In dust, in rain, in cold, and sultry skies;
Fave but the grain from mildew and the flood,
Nought anxious he what sickly stars ascend,
He knows no laws by Esculapius given,
He studies none."

In plain prose, a man who uses much corporal exercise, in open air, may be uncleanly in his person without apparent injury to his health, as well as neglect other rules, which must be conformed to by sedentary persons, and those who exercise the mind instead of the body, if they would preserve the first and most important of temporal blessings.

Bathing among the ancients made a part of diet, and was used as familiarly as eating or sleep; both cold and warm bathing were likewise in high esteem among their physicians for the cure of diseases.

"In ancient times, when Rome with Athens vied
For polish'd luxury and useful arts;
All hot and reeking from the Olympic strife,
And warm Ætæstra, in the tepid bath,
The athletic youth relax'd their wearied limbs."

Among the Turks bathing forms a part of diet and of religion as well as of luxury and a

mean of preserving and restoring health. In every town, and even village, there is a public bath, for those who have not the convenience of private baths attached to their own houses. By these baths, they prevent or dispel rheumatism, catarrhs, and such cutaneous disorders, are produced by want of perspiration. The blood is made to circulate with freedom, the whole body acquires a suppleness and liness, and the spirits gain a vivacity and firmness, which are not experienced in an equal degree by those who do not pay so much attention to external cleanliness. The women are particularly fond of these baths, and frequent them at least once a week. The linen and cloth which they use are passed through the steam of the wood of aloes. The days appropriated to the use of the bath are festival among the Egyptian women; and on this occasion they pay great attention to the ornaments of their dress, as well as to the cleanliness of their persons.*

In Russia, the bath forms so essential a part of the system of living, that it is used by people of every age, and in all circumstances, by faints, by lying-in women, in almost all sicknesses, before and after a journey, after labor, &c. The bath is a necessary of life indispensable to the common people, that they frequent it as often as possible, well or ill, without any particular occasion, once a week at least. The Russian baths are, generally, what are denominated "sweating baths." They are vapor baths, not water, nor yet dry sweating baths; differing in this respect from all baths of antiquity, as well as from those of modern Orientals; and in this consists their essential excellence, that they are beneficial in a variety of cases, where hot water baths would be useless if not pernicious. All the invocations of effeminacy and luxury are entirely obviated in the use of these baths, and there is noointing after bathing as was practised by the Greeks and Romans. Instead of such practice the Russian bathers will throw themselves immediately from the bath-room into an adjoining river, or roll themselves naked in the first bank. It is said by medical men, acquainted with the subject, that the Russians owe their longevity, their robust state of health, and little disposition to certain mortal diseases, their happy and cheerful temper, principally to these baths, though climate, aliment, and habit of living likewise contribute their share.

"The great lord Chancellor Bacon, and other sagacious observers of nature, and of mankind, have lamented, and certainly not without cause, that the practice of bathing has fallen into disuse among the modern nations of Europe, and anxiously wish that it might again revive in our towns and villages. In fact, when we consider, says Mr. Tooke, that the old physicians so early introduced into their practice the remedy of nature's own invention, and employed it with such great success; when we recollect that Rome, for 500 years, had no physicians but only baths, and that to this day a multitude of nations cure almost all their maladies by baths, we cannot avoid regarding the discovery of them as the epocha of a grand revolution which has been wrought in the physical state of the human race, in one quarter

* See Savary's Travels.

ld. The natural perspiration, the most important of all excretions, must naturally go on in a body kept constantly soft by bathing; impurities that privily lay in us the train of dangerous distempers, are removed in time, before they poison the blood and veins.*

We think nothing more need be said to prove the utility of bathing. But this, like all other things, is liable to abuse. Cold or warm bathing, excessively or improperly used, is injurious. Every body knows, who is in the least conversant with ancient history, that Alexander had nearly lost his life by plunging, heated and exhausted, into the river Danube. The cold bath was successfully used in the recovery of the Emperor Augustus from a dangerous sickness, but the same application was supposed to have proved fatal to his heir apparent, Marcellus. Like other powerful remedies, it ought not to be (although it too frequently is) tampered with. With good advice, before, go into water, whether warm or cold. A better not bathe at all, than not bathe at all. Armstrong, celebrated both as a physician and a poet, touches on this subject in the following lines:

Those who from the frozen Arctos reach
And Mauritania, or the sultry West,
A wide flood through rich Indostan roll'd,
Give thrice a day, and in the tepid wave
Just their stubborn pores; that full and free
Evaporation through the sotten'd skin
Bear proportion to the swelling blood;
All they escape the fever's rapid flames.
But the man of no complaint demands
Warm ablution, just enough to clear
The juices of the skin, enough to keep
The body sacred from indecent soil."

These directions, however, are rather poetical than practical, and tend more to amuse the reader than to enlighten the understanding.—withstanding the great importance of bathing as a mean of preserving health, or healing diseases, nothing definite, nothing scientific has, within a few years, been published on the subject. As Dr. Coffin well observes in the preface to the Treatise which is the subject of this notice, "The principles of bathing have been but little studied, or the practice rationally adopted in the United States; indeed than our general advancement in civilization, or the present improvement in the mode of preventing and curing diseases would lead one to expect or desire." A number of late publications on this topic, have appeared in Europe, but they are not only numerous, but inaccessible to the great body of the community. Such a work as the one we now present, was, therefore, very much wanted, and ought to be read by every person capable of reading and reflection, to whom health and cleanliness are objects worth attention. The benefits of bathing in autumn we shall not repeat the remarks, furnished by a medical writer, whose science, judgment, and experience may be relied on.

Some persons think that so soon as the hot weather abates, bathing may be discontinued at once. But this is so far from being true, there are some peculiar advantages to be derived from continuing the practice in that season. One is that the bath enables us to sur-

mount the languor, which the preceding heat has induced. Another is that bathing prepares us to meet the approaching cold of winter without inconvenience and without danger; so that we neither suffer from a sense of cold, nor fall sick from the gradual changes of the seasons from summer and autumn to winter. Bathing, too, is one of the greatest preventives of autumnal fevers; for proof of this take the following facts from Dr. Currie.

In the year 1792, a regiment of troops was stationed in Liverpool, England. Their general guard-room had been previously used as a place of confinement for deserters. It was extremely close and dirty, and under it was a cellar, which in the winter had been full of water. This water was now half evaporated, and from the surface issued offensive exhalations. In a dark, narrow and unventilated cell, it was usual to confine such men as were sent to the guard for misbehavior, and about the 20th of May, several men had been shut up in this place on account of drunkenness, and suffered to remain here twenty-four hours, under the debility that succeeds intoxication. The typhus, or jail fever, made its appearance in two of these men, about the first of June, and spread with great rapidity.

"Ten of the soldiers laboring under this epidemic, were received into the Liverpool Infirmary, and the wards allotted to fever could admit no more. The infection continuing its progress, a temporary hospital was fitted up at the fort, and I was requested to give my assistance. In two rooms, each about 15 feet square, were fourteen patients laboring under fever.—The symptoms of the disease were, more or less of cough, with mucous expectoration. In all those who had sustained the disease eight days or more, there were *petechiæ** on the skin, in several there were occasional bleedings from the nostrils, and streaks of blood in the expectoration. Debility was considerable from the first; the pulse varied from 100 to 130 strokes in the minute; heat from 101 to 103 degrees. Great pain in the head, with stupor, pervaded the whole, and in several instances a low delirium. Our first care was to ventilate and clean the room; our second, to wash and clean the patients themselves. Our third object was to stop the progress of the infection. We first attempted to purify the guard room, but this was found to be impracticable. The weather being wet and cold, the men on guard could not be prevailed on to remain in the open air; and from passing the nights in the infected guard room, several privates of the successive reliefs caught the infection, and fell ill on the 10th, 11th and 12th of the month. In several of these the fever ran through its course; and in others it was immediately arrested by the affusion of sea water over the body.

"The infected guard room was shut up, and a temporary shed erected in its stead. Still the infection proceeded; on the 13th, three more having been added to the sick list. On this day therefore the whole regiment were drawn up at my request, and the men examined in their ranks; seventeen were found with symptoms of fever; it was not difficult to distinguish these as they stood by their fellows. Their countenances were languid, their whole appearance dejected, and their eyes had a dull red suffusion. These men were carefully separated from the rest of the corps, and immediately subjected to the cold affusion of water, always repeated once and sometimes twice a day. In fifteen of the number the disease was extinguished; two only went through the fever. On the same day the commanding officer, at my desire, issued an order for the whole remaining part of the regiment to bathe in the sea; and for sometime they were regularly mustered, and marched down at high water, to plunge into the tide.—These means were successful in arresting the epidemic. After the 15th of June no person was attacked by it. Fifty-eight had the disease—thirty-two went through its regular course, and in twenty-six the fever seemed to be cut short by the cold affusion. Two only died, and both of these had been enfeebled by a West India climate, and by other causes.

"Several instances have come to my knowledge, of individuals who had during a number of years usually suffered from autumnal fever and rheumatism, but who, after a regular course of sea, or other cold bathing, have escaped these complaints. In these cases there has been a sensible increase of strength, diminished tenderness in regard to the sensation of cold, and less liability to catarrh from the ordinary atmospheric changes of the season. In this way the preventive operation of bathing can be readily understood."

Having already protracted this article to an extent beyond our intended limits, we must omit giving quotations from the work of Dr. Coffin, which we would wish to recommend, rather than attempt to criticize or review.—Perhaps we may again advert to it, particularly that part which is entitled "Remarks on the effects of drinking cold water in warm weather." We would, however, before we dismiss the subject of bathing, recommend to the consideration of innkeepers, whether it would not be pleasant, profitable and salubrious, to establish cold and warm baths, especially the latter, at their houses of entertainment? The weary and way-worn traveller may frequently derive more refreshment from five minutes bathing in a warm bath, than from as many hours spent in attempting to repose on a bed of down. Warm bathing dispels fatigue, as it were, by magic, and gives a predisposition to enjoy the benefits of a tired nature's sweet restorer, balmy sleep, which are often sought in vain by those to whom violent and long continued exercise have rendered them peculiarly necessary.

We will now close our recommendation of bathing, and the treatise which directs when and how the bath is to be used, which gave occasion to these remarks, with one other quotation from a favorite poet, whose maxims are well calculated to lessen the miseries of human life.

"We will now close our recommendation of bathing, and the treatise which directs when and how the bath is to be used, which gave occasion to these remarks, with one other quotation from a favorite poet, whose maxims are well calculated to lessen the miseries of human life."

"Still to be pure, e'en did it not conduce
(As much it does) to health, were greatly worth
Your daily pains. 'Tis this adorns the rich;
The want of this is poverty's worst woe;
With this external virtue, age maintains
A decent grace; without it, youth and charms
Are loathsome. This should maidens know,
As doubtless do your wives; for married sires
As well as lovers, still pretend to taste;
Nor is it less, (all prudent wives can tell)
To lose a husband's than a lover's heart."

From the Massachusetts Agricultural Repository.

ESSAYS ON FLAX HUSBANDRY.

BY S. W. POMEROY, ESQ.

First Vice President of the Massachusetts Society for Promoting Agriculture.

No. II.

Notwithstanding it is an opinion well established among experienced flax growers in this country, that a change of seed is advantageous, it is apprehended that they are not aware of the extent of the benefit to be derived by selecting seed from a soil or climate essentially different; and it may be owing to a want of attention in this particular that the flax crops are so uncertain and the quality inferior, however perfect in other respects the system may be conducted. Mr. Young observes that foreign flax seed was universally used in Ireland, when it could be obtained, otherwise they were careful to procure seed which grew upon soil of an opposite quality from that which was to be sown, that American seed was to be preferred, and produced finer flax than any other. Baltic seed produced more but of a coarser quality. It is well known that American seed always bears the highest price in the Irish market.

We next look to Flanders, where flax was cultivated at a period as early as the commencement of the christian era.* Fortunately we are furnished with "directions for cultivating flax after the Flanders method" published by commissioners and trustees appointed by the British government to promote the linen trade in Scotland, at the head of whom was the celebrated Lord Kaims; from this high authority we learn that it was the practice "to sow seed imported from Riga, if it could be obtained, otherwise the produce of Riga seed sown in Holland, and if that could not be had, that which Riga seed had produced in their own country, being careful to choose that which had grown on soil of a different texture and quality. What is the practice in Germany, where the cultivation is very extensive? By a respectable British publication, now before me, in which an account is given of the trade of Stettin, a city of Prussian Pomerania, situated near the mouth of the river Oder, it appears that the extent of the linen trade is estimated by the quantity of Flax-seed imported; and it is stated that on an average of ten years preceding 1796, twenty-one thousand, six hundred and forty-five tons of Flax-seed were annually imported into that port, to be sent up the Oder and the waters connected with it, which, at forty bushels to the ton, amounted to upwards of eight hundred thousand bushels; sufficient for half a million of acres at the rate it is sown in this country! and it is not improbable that large quantities are imported into other ports connected with the German rivers.

Foreign Flaxseed was sought after even in the remote valleys of Switzerland, as appears by the following extract from a treatise on the culture of Flax by Mr. Tschiffeli, president of the economical society of Bern. "In general the best flax-seed is produced on strong soils, and in cold climates. Experience has long convinced us that what is brought from Livonia" (Riga seed) "is to be preferred to all others,

but when this cannot be procured, we must make use of that which grows on our own mountains, for instance Gessenai, Jura," &c.

A Flemish colony first settled the island of Fayal, and introduced Flax. They have become amalgamated with the Portuguese, but the culture, and manufacture of linen in families, has continued to an extent nearly equal to the clothing and general consumption of a very dense population. The soil is mostly in tillage, and from its elevation admits of a variety of aspect and temperature, and a great care is bestowed on the culture of flax. I have been informed by Mr. Dabney, the United States consul for the Azores, who has resided fifteen years at Fayal, that American seed, obtained from ships bound to Ireland, arriving in distress, has been sown; and the product, in flax and seed, has been fifty per cent. more than from that of native growth by the side of it! We have no information to this point from Russia or Italy; but it is believed that examples enough have been cited to shew the importance attached to this branch of the system in Europe, and to justify the conclusion that in this country a continued, judicious change of seed will be indispensable to the successful prosecution of flax husbandry; and a further inference may be drawn, that experiments on various soils with seed the growth of different climates, are requisite to direct the farmer to the quarter from whence his best seed may be obtained. Here opens a legitimate field for our numerous agricultural societies to labor in; on their exertions the farmer must depend in the outset; but let it once be ascertained that Riga seed is best in one section, Dutch or German in others, and mercantile interest, if not patriotism, will soon distribute them.

Should it be objected to importing seed on account of the expense, we reply, that large quantities of linseed oil are constantly imported, and the difference of price between our own seed and that imported, will not much exceed what is now paid for good clean seed for sowing or export, and that which is sold for crushing; but if it is fifty cents per bushel, or more, it can be no object, compared with the advantages that may be reasonably expected to result, and the farmer need not be told, that "in all his operations, parsimony is never so ill judged, as when exercised in the selection of his seed." It is not pretended, however, but that, from the great variety of soil and climate in the United States, the object in view might be obtained without importations; yet, it may be important to have a good stock to begin with, when trials could be instituted with its produce; at any rate it cannot be expected that individuals will embark in such a course of experiments, either with foreign or domestic seed, unless encouraged by agricultural societies or other public bodies.

SOILS.

The subject presents a character of such national importance, that a wider range must be taken than views of mere local interests require; we shall therefore first examine, under the present head, the different sections of our country. New soils are found most favorable to the growth of the flax plant; and it is scarcely necessary to mention the vast fertile tracts on the western waters, as capable of producing immense quantities.

The State of Maine has a soil and climate that appears highly congenial to flax culture. The extensive tracts of strong carbonaceous soils, particularly those denominated "black lands," and the almost total absence of drought will enable that state to possess a staple in the article, not inferior in value to any, except grazing, whenever the energies of her population shall be directed to it. The rest of New England, that part of New York not included in the first description, and New Jersey, large bodies of land suitable for flax, quite sufficient to be embraced in the system of agriculture best adapted to their situation. Pennsylvania probably grows more flax than all the other states in the union.* The Atlantic sections, the states, south of the Delaware to the cotton latitude, possess considerable tracts of alluvial soils, bordering on the numerous rivers, bays, and inlets, with which they are intersected; portion of them, besides swamps, may be reclaimed without great expense; they have so bodies of strong clays. Should these be too much exhausted by severe cropping, they may soon be restored by the admirable clover system adopted by Col. Taylor of Virginia, a mode to produce good flax; as it is probable from the early period the ground may be sown that the crop would be seldom injured by the droughts to which the climate is subject.

The soils which rank first in this country are the flat bottoms, that are covered by the fall and spring floods which subside early enough in the season to get in a crop; those on the flats on the second banks, that have a deep of strong alluvial soil; the reclaimed marsh and swamps with a black unctuous soil, not peaty, with as much clay in the composition will permit its being rendered soon dry; mellow, and not retain water on or near the surface; if it stands two feet below, so much the better, but must be well guarded by dikes and dykes against sudden freshets. Such is soil of the province of Zealand, where in flax is raised and of better quality, than in other part of Holland. The next in estimation are the strong black loams on clay, or hard that will retain moisture. Yellow loams, with a holding subsoil, may be rendered suitable flax by proper cultivation; and since the discovery that plaster of Paris is an excellent manure for it, a crop may be obtained with more certainty on lighter land than formerly. Perhaps the characteristic of best garden manure may be applied to a flax soil, viz. retaining sufficient moisture, and all that falls, without being saturated; but on any soils the soil should be completely pulverized, and well worked when wet.

MANURES.

No dung should be applied to the land where the flax is sown, but may be put on bountifully with the previous crop. The objection is, dung forces the growth so rapidly that the plant draws weak, have a thin harle, and are unable to lodge. Lime, marle, shells, leach ashes, &c. do not produce such effects. Dressings, soon after the plants appear, of lime, ashes, soot, &c. are highly beneficial.

* By the returns of the Marshals in 1810, there manufactured in the United States \$80,000 worth of Linseed Oil; \$500,000 of which was made in Pennsylvania, and \$200,000 in New England.—See Statement.

* Pliny's Natural History, book 19.

† Commercial Agricultural Magazine, vol. iii. 1800.

they not only encourage the growth, but are a protection against worms, which sometimes attack the young plants, and may be considered the only enemy they have, except weeds.

Salt has been mentioned by the late Dr. Eliot, of Connecticut, as an excellent manure to plough in with flax at the rate of five bushels to the acre;* probably more would be better. Plaster is now much used in Dutchess county, the best cultivated district in New York, as a manure for flax, on which its good effects are apparent as on corn.

The late chancellor Livingston viewed a piece of flax on the 20th of May, 1791, belonging to a poor tenant, very injudiciously sown in a dry sandy declivity, it looked so extremely sickly that the tenant thought of ploughing up; the chancellor gave him three bushels of Plaster, which was sown the next morning before the dew was off, and had the satisfaction of seeing his tenant gather more flax from his half acre in an uncommon dry season, than was produced from any acre in the neighborhood.

PREPARATION OF THE LAND.

It is not unfrequent in Ireland to obtain crops of flax from green sward, on which they put peat, shells, limestone, gravel, &c. and break it in the fall, cross ploughing and harrowing in the spring; but it most commonly succeeds a crop of potatoes which receive the manure. In Flanders, Hemp was formerly more used as a preparation for flax than since the introduction of potatoes. In Italy it commonly succeeds flax, and although the land gets no tillage, as the hemp is well manured it grows strong, and is then a powerful destroyer of weeds. In England, on some of the few soils of a cold nature, the usual course is hemp 2 or 3 years in succession, well manured, then flax without manure; a crop of turnips is often taken the same season after the flax, and hemp succeeds again. In Russia it is said that extensive crops of flax are drawn from new cleared lands after burning them over, and harrowing the seed with ashes. The best preparatory crops in this country, at present, appear to be potatoes, corn and roots; they will most generally repay the extra manure, and if well managed check the production of weeds.

The following rotations may serve as an outline, subject to be varied, and hemp or other crops introduced as circumstances require, viz:

No. I. Low, cold or reclaimed Soils.

1st year Potatoes.
2d do. FLAX with seed.
3d do. Herds grass and red top or tall meadow grass, to continue three years or more, and the course repeated.

No. II. Strong Uplands.

1st year Potatoes or Corn.
2d do. Corn or Roots.
3d do. FLAX with seed.
4th do. Clover.
5th do. Orchard grass or Herds grass, to continue three years or more.

No. III. Light Lands.

1st year Potatoes or Corn.
2d do. Corn or Roots.
3d do. FLAX with seed.
4th do. Clover, to be mown once, the after

growth to be turned in and Rye sown, thick on the furrow, which may be soiled or fed in the spring by sheep or milch cows, and ploughed in; for

5th year Corn.

6th do. Spring Wheat or Barley.

7th do. Clover, and the course to be pursued as before, when flax will occupy the land every seventh year. In all cases, except when hemp is substituted, the tillage crops should receive the dung.

If the land is ploughed into beds, or convex ridges like turnpike roads about a rod wide, especially if low and level, the crop will be much more secure from injury by heavy rains, and the grass crops will be better if it remains in that form. On any soils, fall ploughing in narrow ridges will facilitate its early working in spring, and should not be dispensed with.

CHOICE OF SEED.

That of the last year's growth should be obtained if possible. The usual marks of good seed are, that it be plump, oily and heavy, of a bright brown colour, sinking readily in water, and when thrown into the fire to crackle and blaze quick. A very simple method of trial is to sprinkle it thin between two pieces of wet paper, which plunge in a hot bed or dung-hill, and in less than twenty-four hours the proportion that will vegetate can be discerned, which should be ascertained in order to regulate the

QUANTITY TO BE SOWN.

On this head no particular directions can be given, as it depends on the various qualities of soil, goodness of seed, &c. The rule for seeding small grains is reversed; flax requiring to be sown thickest on rich soil, as not more than one stock is wanted from a plant. In England and Scotland, never less than two, or more than three bushels to the acre are sown. Two and a half is the most usual portion. In Flanders and Ireland seldom less than three bushels are sown, except when seed is an object. Thick sowing is to obtain fine flax. In this country it will be important, at present, to sow at such a rate as will insure good crops of each; and experience only can determine the exact point.

If sown very thin, too many lateral branches will be thrown out, each producing a boll or pod affording more seed, but shorter and inferior flax. If sown too thick, the plants will draw up weak, with a single holl on a plant, and, subject as our climate is to heavy showers and thunder gusts, very liable to lodge—one of the greatest dangers a flax crop has to encounter. The commissions for promoting flax culture in Scotland, considered it as practicable, and strongly recommended that the system should be so conducted, as to obtain good flax and good seed at the same time. It is so viewed in Ireland, among the more extensive cultivators, except when wanted for fine linen, cambric, lawn, &c. Dr. Deane, in the "New-England Farmer," a work of great merit, published some thirty years since, when flax culture was more attended to than at present, recommends from six to seven pecks. It is probable that six pecks is the least, and two bushels the extent that should be sown to obtain the most profitable results, till the demand for seed is considerably lessened.*

*The demand for Linseed Oil must increase with the population for some time to come, as there appear

Mahogany.—The difficulty of procuring mahogany, and other costly woods, and the consequent exorbitant prices demanded for the ordinary articles of family convenience, has occasioned the art of the chemist to be applied to a subject peculiarly calculated to promote domestic embellishment at a trifling expense. It has been contrived to render any species of wood of a close grain so nearly to resemble mahogany in the texture, density, and polish, that the most accurate judges are incapable of distinguishing between this happy imitation and the native produce. The first operation, as now practised in France, is to plane the surface, so as to render it perfectly smooth; the wood is then to be rubbed with a solution of nitrous acid, which prepares it for the materials subsequently to be applied. Afterwards, one ounce and an half of dragon's blood, dissolved in a pint of spirits of wine, and one third of that quantity of carbonate of soda, are to be mixed together and filtered, and the liquid in this thin state is to be rubbed, or rather laid on the wood with a soft brush.—This process is repeated with very little alteration, and, in a short interval afterwards, the wood possesses the external appearance we have described. When this application has been properly made, the surface will resemble an artificial mirror; but if the polish becomes less brilliant, by the use of a little cold-drawn linseed oil, the wood will be restored to its former brilliancy.

It is not known, perhaps, so generally as it ought to be, that apples make an excellent jelly. The process is as follows:—They are to be pared, quartered, the core completely removed, and put into a pot without water, closely covered, and placed in an oven over a fire. When pretty well stewed, the juice is to be squeezed out through a cloth, to which a little white of egg is added, and then the sugar. Skim it previous to boiling, then reduce it to a proper consistence, and an excellent jelly will be the product.—*U. S. Gazette.*

DR. GREEN'S CURE FOR DRUNKENNESS.

Whenever you feel an inclination to drink spiritous liquor, (Grog) drink cool—fresh water. This is an effectual cure: and, in a very short time, you will make a sober man—out of the greatest drunkard.

Drunkenness (the Doctor says,) is a disease of the stomach, and cool water is the remedy. For the goodness of Providence has placed by the side of every disease, its appropriate remedy; and by the side of every evil, its appropriate good. Let us be thankful.

In an answer of the Doctor to a letter I sent him, relative to my sickness, and drinking spiritous liquor, it contained in substance, what I now write; and thank Providence, it has perfectly cured me of that dreadful disease, called drunkenness.

I can now attend to my business, and can say, that a sober life is a good life—a saving of many things—'tis a saving of cash—'tis a saving of the constitution—'tis a saving of a man's credit.—*Massachusetts Spy.*

no indications that the people will forsake their household deities, Clapboards and Paint, 'till the soil is much more denuded of its timber; even in those districts where the roads and fields are incumbered with suitable materials for permanent, cheaper, and more elegant buildings.

See Eliot's Essays on Field Husbandry.

Transactions of Agricultural Society, New York.

From the American Farmer.
FURTHER INFORMATION ON THE CURING
OF HOPS.

Beverly, 4th July, 1823.

Gorham Parsons, Esq.

Dear Sir—I do not keep a copy of the letter I wrote you respecting the culture and curing of hops, and I do not recollect particularly the further information you requested of me, but I believe it was principally respecting the kiln.

A kiln for the purpose of drying hops should be at the side of a hill or rising ground, so that the top should be about nine feet from the bottom, twelve feet square at the top, tapering on all sides to about three and a half feet at the bottom in the clear, built up tapering, with stone laid in lime mortar, and plastered with clay from top to bottom with an aperture at the bottom about the size of the mouth of a common oven, for the convenience of putting in the coal, firing it, and regulating it afterwards.

Upon the stones at the top, is placed a sill of four pieces of timber of about eight inches square, and of course about twelve feet long, that being the size of the kiln at the top, upon which you place strips of boards, half inch thick and two inches wide, and within three and a half to four inches of each other, over which you stretch tow or coarse linen cloth, for a bed to place the hops upon, for the purpose of drying, and under which, at the bottom of the kiln, is made a charcoal fire, regulated at the discretion of the man who attends the drying. It will of course be necessary to have a board round the kiln at the top, of about one foot high, to confine the hops on the bed. I think it would be a further improvement to have a covered roof, and open at the sides, to protect the hops in case of rain, while they are drying.

It will be necessary to stir them constantly with a rake, while they are drying, and you may with convenience dry about fifty pounds each time. I believe you may calculate about one pound to a hill, or 800 lbs. to the acre, for the second and third year, after planting, if the land is in good order. It will be well to renew your fields once in three or four years, because the vine degenerates.

I am, dear Sir, with great respect,

Your friend and obedient servant,
ISRAEL THORNDIKE.

NEW ENGLAND FARMER.

SATURDAY, AUGUST 30, 1823.

Several communications were received too late for this day's paper. They will be given next week.

The Trustees of the Massachusetts Agricultural Society cannot omit the opportunity of tendering, publicly, their thanks to Captain Jackson, of the Ship Herald, for the great care and attention bestowed by him on their fine imported bull, Admiral, presented to the Society by Sir Isaac Coffin, without which care he must probably have perished during his long and boisterous passage. This example is worthy of imitation, as upon the patriotic assiduity of Ship-masters often depends the acquisition of plants and animals, which may prove of importance to their country.

In behalf of the Trustees,
JOHN LOWELL, President.

Roxbury, August 23, 1823.

Extracts from a work lately published by WILLIAM CORBETT, entitled "*Cottage Economy*," with occasional remarks on some of the statements of the author.

[Continued from page 30.]

"If the laborer have his fair wages; if there be no false weights and measures, whether of money or of goods, by which he is defrauded; if the laws be equal in their effect on all men; if he be called upon for no more than his due share of the expenses necessary to support the government and defend the country, he has no reason to complain. If the largeness of his family demand extraordinary labor and care, these are due from him to it. He is the cause of the existence of that family; and, therefore, he is not, except in cases of accidental calamity, to throw upon others the burthen of supporting it. Besides, 'little children are as arrows in the hands of the giant, and blessed is the man that hath his quiver full of them.' That is to say children, if they bring their cares, bring also their pleasures and solid advantages. They become, very soon, so many assistants and props to the parents, who when old age comes on, are amply repaid for all the toil and all the cares that children have occasioned in their infancy. To be without sure and safe friends in the world makes life not worth having; and whom can we be so sure of as our children. Brothers and sisters are a mutual support. We see them, in almost every case, grow up into prosperity, when they act the part that the impulses of nature prescribe. When cordially united, a father and sons, or a family of brothers and sisters, may, in almost any state of life, set what is called misfortune at defiance.

"These considerations are much more than enough to sweeten the toils and cares of parents, and to make them regard every additional child as an additional blessing. But, that children may be a blessing and not a curse, care must be taken of their education. This word has, of late years, been so perverted, so corrupted, so abused, in its application, that I am almost afraid to use it here. Yet I must not suffer it to be usurped by cant and tyranny. I must use it; but, not without clearly saying what I mean.

"Education means *breeding up, bringing up, or rearing up*; and nothing more. This includes every thing with regard to the *mind* as well as the *body* of the child; but of late years, it has been so used as to have no sense applied to it but that of *book learning*, with which, nine times out of ten, it has nothing at all to do. It is, indeed, proper, and it is the duty, of every parent, to teach, or cause to be taught, their children as much as they can of books, *after*, and not before, all the measures are safely taken for enabling them to get their living by labor, or, for procuring them a living without labor, and that too, out of the means obtained and secured by the parents out of their own income. The taste of the times unhappily, is to give to children something of *book-learning* with a view of placing them to live, in some way or other, upon the labor of other people. Very seldom, comparatively speaking, has this succeeded, even during the wasteful public expenditure of the last thirty years; and, in the times that are approaching, it cannot, I thank God, succeed at all. When the project has failed, what disappointment, mortification and misery, to both parent and child! The latter is spoiled as a laborer; his book-learning has only made him conceited;

into some course of desperation he falls; and the end is but too often not only wretched but ignominious.

"Understand me clearly here, however; for it is the duty of parents to give, if they are able, book learning to their children, having first taken care to make them capable of earning their living by *bodily labor*. When that object has once been secured, the other may, if the ability remain, be attended to. But, I am wholly against children wasting their time in the idleness of what is called *education*; and particularly in schools over which the parents have no control, and where nothing is taught but the rudiments of servility, pauperism and slavery.

"The education that I have in view is, therefore, of a very different kind. You should bear constantly in mind, that nine tenths of us are, from the very nature and necessities of the world, born to gain our livelihood by the sweat of our brow. What reason have we, then, to presume, that our children are not to do the same? If they be, as now and then one will be, endowed with extraordinary powers of mind, those powers may have an opportunity of developing themselves; and, if they never have that opportunity, the harm is not very great to us or to them. Nor does it hence follow, that the descendants of laborers are *always* to be laborers. The path upwards is steep and long, to be sure, industry, care, skill, excellence in the present parent lays the foundation of a *rise*, under more favorable circumstances, for his children. The children of these take *another rise*; and, by and by, the descendants of the present laborer become gentlemen.

"This is the natural progress. It is by attempting to reach the top at a *single leap* that so much misery is produced in the world; and the propensity to make such attempts has been cherished and encouraged by the strange projects that we have witnessed of late years for making the laborers *virtuous and happy* by giving them what is called *education*. The education which I speak of consists in bringing children up to labor with *steadiness*, with *care*, and with *skill*; to show them how to do as many useful things as possible; to teach them to do them all in the best manner; to set them an example in industry, sobriety, cleanliness and neatness; to make all these *habits* to them, so that they never shall be liable to fall into the contrary; to let them always see a *good living* proceeding from *labor*, and thus to remove from them the temptation to get at the goods of others by violent or fraudulent means, and to keep far from their minds all the inducements to hypocrisy and deceit.

"And, bear in mind, that, if the state of the laborer has its disadvantages when compared with other callings and conditions of life, it has also its advantages. It is free from the torments of ambition, and from a great part of the causes of ill-health, for which not all the riches in the world and all the circumstances of high rank are a compensation. The able and prudent laborer is always *safe*, at the least, and that is what few men are who are lifted above him. They have losses and crosses to fear, the very thought of which never enters his mind, if he act well his part towards himself, his family and his neighbor."

The foregoing sentiments are perfectly correct and happily expressed. The following,

translated from Rousseau, is to the same purpose, and may serve to corroborate Mr. Cobbett's views on a very important subject. "In the education of your children you seem to trust to the state of society's continuing the same when they are grown up, without considering that it is subject to revolutions which it is impossible for you to foresee or prevent, but which may affect your children. The great become little, the rich poor, the king a subject, and the subject a king. Agriculture is the first employment of man; it is the most honest, the most useful, and consequently the most noble. It is, instead of, or in addition to, superior mental requirements, you could, in time of necessity, employ your hands, all your difficulties would vanish, nor would you want the interest of the great, or be tempted to become servile and base for the purpose of gaining a precarious subsistence."

(TO BE CONTINUED.)

HORTICULTURE.

The London Horticultural Society has lately sent to this country Mr. Daniel Douglas, an eminent botanist, for the purpose of collecting specimens of rare plants, vegetables, fruits, &c. in the United States and Canada. Mr. Douglas has directions to call on Dr. Hosack, of New York, and Mr. Clinton, at Albany, for their advice and aid in the objects of his agency. These gentlemen are honorary members of the Horticultural Society of London, and have contributed to its objects. Dr. Hosack has sent to the Society all the varieties of maize which are found in the U. States, &c. It has been presented with an elegant medal. Mr. Douglas proposes to visit Philadelphia and its environs, together with New Jersey, with a view to the objects of his tour—to return to New York, explore the gardens, &c. in the vicinity of that city—to advise with Mr. Clinton with respect to his route to Niagara through the Western counties of the State of N. York, and then proceed to Upper Canada. The New York Statesman (from which paper this article is abridged,) says "the ructions of Mr. Sabine, the Secretary of the London Society, who is understood to be a gentleman eminent in his scientific attainments, breathe a spirit of liberality and good feeling towards this country, and some of its distinguished citizens, which have not on all occasions characterised the intercourse of foreigners. We are gratified to learn that measures have been taken for opening a correspondence between the Horticultural Societies of London and of New York. The institution in this city is yet in its infancy, while that in London has been long established, and has become one of the most respectable and valuable associations in England. Its transactions, the last two numbers of which have just been received by Dr. Hosack, are published in a very superior style with plates, and contain a great variety of interesting matter."

We hope that these examples will excite our New England cultivators to honorable and profitable emulation. Mr. Lowell, in the last and several of the preceding numbers of the Massachusetts Agricultural Reporter, has so well exhibited the advantages which may be anticipated from a due attention to this important branch of Husbandry, that any suggestions from us relating to the same subject might be deemed superfluous. We shall therefore merely remark that our soil and climate afford greater facilities for the pursuits of horticulture than those of Great Britain. Our winters are colder, but our summer-sun is much more powerful, and we can cultivate in New England many plants, including maize, melons, &c. in the open air by ordinary means, which in Great Britain require artificial heat and other means to counteract the moisture and coldness of an atmosphere, ungenial to some of the productions both of the field and the garden.

New England Farmer, vol. i, p. 11, 412.

FOREIGN.

An arrival at N. York on the 25th inst. has brought Cadiz papers to the 10th of July. Cadiz was, at that time, well supplied with provisions, and no fears were entertained of a scarcity should the blockade continue for several months. Provisions were likewise cheap and plentiful at Algeiras, San Fernando and St. Sebastian. The French blockading squadron are unable to prevent small vessels and boats from entering the port of Cadiz, laden with provisions.

The Cortes, it is said, are zealously and industriously engaged in measures for the defence of the country. They have authorized the commanding generals in places besieged, and those whose commanders cannot conveniently communicate with the government at Cadiz, to establish special tribunals for the trial and punishment of crimes, and likewise to banish suspicious foreigners.

An English brig, laden with provisions, attempting to go into Cadiz, was boarded from the blockading squadron, most of her cargo thrown overboard, and the residue destroyed with salt water. A brig belonging to Wm. Gray, of Boston, had been ordered off and proceeded to Malaga. A Sardinian merchantman, with 500 quintals of cod fish, bound from Gibraltar to Lisbon, was detained three leagues from Cadiz, and her cargo thrown overboard.

Cadiz articles affirm that Moillo goes on organizing his army, which he has put on a brilliant footing.—The French who had arrived near Astorga, suddenly retired to Palencia.—That several private letters received from Corunna, state that a French division of 6000 men had made a precipitate retreat across the Pyrenees. This, however, is not believed. General Zayas, commander of the third army of operations, gives favorable intelligence relative to the troops under his command.

Gen. Ballasteros sent a despatch to Cadiz, stating in detail, some occurrences connected with his late retreat from Alceira. He says that on the Royale road the French cavalry charged his infantry, but were repulsed in a contest hand to hand, and several French officers killed. He likewise asserts that Alicante and Carthage were sufficiently garrisoned, and that his army will not be destroyed while he remains at its head—but he laments the effects of a wound which he received from a cannon ball at the battle of Murviedo. It is also reported that the garrison of Santona, in a sortie, had captured 250 prisoners, and 45,000 dollars in specie.

DOMESTIC.

Retreat for the Insane.—An act of the Legislature of Connecticut was passed in May, 1822, for constituting certain persons a corporation by the name of "The President and Directors of the Retreat for the Insane," and the Governor authorized and requested to grant a Brief, annually, for five years, soliciting contributions for the benefit of this institution. A Proclamation by Gov. Wolcott has been issued accordingly, and Directors appointed, who have made a purchase of a site for the Retreat, erected a building, and there is a prospect of their proceeding with a degree of success proportioned to the utility of the object.

Globe Factory.—Messrs. Wilsons, of Albany, have established a manufactory for making globes, and the Albany Daily Advertiser says, that "these native and self-taught artisans have brought their business to such perfection that they can turn out Globes, in all respects equal, and in some points superior, to any that are manufactured abroad, and brought into this market. It is with pleasure that we learn, an eminent bookseller in Philadelphia has come to the determination not to import any more from abroad, having given a decided preference to those made by the Wilsons." This is said to be the only establishment of the kind in America, and globes can there be obtained at a cheaper rate than they can be afforded from foreign countries.

The new and elegant steam-boat, *James Kent*, plying between N. York and Albany, is of such power as to make each trip up and down the river during the day time, which gives passengers an opportunity of viewing the scenery of the Hudson, through its whole extent.

Another Hunting Party attacked by Indians.—An article published at St. Louis, informs that a party of hunters were passing a narrow defile in the mountains, when a small party of Indians attacked them in front and rear, while the rest threw down stones from the mountains. The two leaders, Messrs. Robert Jones and Imnell, were shot down first. The men, finding themselves left without a commander, took to flight, and were cut to pieces by the Indians.

Indian War.—The Cincinnati papers state, that there was a report in town, "from St. Louis, that Maj. Henry's party spoken of by Gen. Ashley, in his letter of the 4th of June, on their passage from Yellow Stone river had been attacked by a large party of Indians and totally defeated, with a loss of thirty killed. We cannot vouch for the truth of this report, but from the hostile disposition lately manifested by the Indians in that quarter, and the small military force stationed at the posts up the Missouri, we have serious apprehensions of its truth."

On Saturday last the command of the Charleston Naval Station was transferred by Com. Hull to Com. Bainbridge, in pursuance of orders from the Navy Department.

A barn in Pepperell, belonging to Mr. James Lawrence, Jr. was burnt by lightning on Thursday last.

INSCRIPTION IN A HERMITAGE.

Beneath this stony roof reclin'd,
I sooth to peace my pensive mind:
And while, to shade my lowly cave,
Embow'ring elms their umbrage wave;
And while the maple dish is mine,
The beechen cup, un stain'd with wine:
I scorn the gay licentious crowd,
Nor heed the toys that deck the proud.

Within my limits lone and still,
The blackbird pipes in artless trill;
Fast by my couch, congenial guest,
The wren has wove her mossy nest;
From busy scenes and brighter skies,
To lurk with innocence, she flies;
Here hopes in safe repose to dwell,
Nor aught suspects the sylvan cell.

At morn I take my custom'd round,
To mark how buds yon shrubby mound;
And ev'ry op'ning primrose count
That trimly paints my blooming mount:
Or o'er the sculptures, quaint and rude,
That grace my gloomy solitude,
I teach in winding wreaths to stray
Fantastic ivy's gadding spray.

At eve within yon studios nook,
I ope my brass embossed book,
Pourtray'd with many a holy deed
Of martyrs, crown'd with heavenly meed:
Then, as my taper waxes dim,
Chant, ere I sleep, my measur'd hymn;
And, at the close, the gleams behold
Of parting wings bedropt with gold.

While such pure joys my bliss create,
Who but would smile at guilty state?
Who but would wish his holy lot
In calm Oblivion's humble lot?
Who but would ead his pomp away,
To take my staff and amice gray;
And to the world's tumultuous stage
Prefer the blameless hermitage!

From the Providence Journal.

BATTLE OF BENNINGTON.

The following account of the battle of Bennington, is extracted from Thacher's Journal. As the battle was one of the most sanguinary and decisive that was fought during our revolution, the narrative of it must be interesting to every description of readers. The account is not, however, so precise and distinct as could be wished, but it has the happy effect of introducing the reader to a knowledge of the state of our society, at that eventful period.

"It was a providential circumstance that Gen. Stark, was at or near Bennington, with about eight hundred New England militia, part of whom being from the New Hampshire grants, were called Green Mountain boys. He advanced towards the enemy to reconnoitre their position, and some skirmishing ensued, in which thirty of them, with two Indian chiefs were killed and wounded, with little loss on our side. Col. Baum, alarmed at his situation, despatched a messenger to Burgoyne for a reinforcement. The 15th being a very rainy day, there was only some skirmishing in small parties. On the 16th General Stark, assisted by Col. Warner, matured his arrangements for battle—he divided his troops into three divisions, and ordered Colonel Nichols, with two hundred and fifty

men, to gain the rear of the left wing of the enemy, and Col. Hendrick, the rear of their right wing, with three hundred men, while he attacked their front.—The Indians alarmed at the appearance of being surrounded endeavored to make their escape in a single file between the two parties, with their horrid yells and jangling of cow-bells. The flanking parties approaching each other in their rear, and Gen. Stark, making a bold and furious onset in front, a general and close conflict ensued, and continued with more or less severity for about two hours. Though Col. Baum had nearly twice their numbers, and was defended by breast works, the force opposed them proved irresistible, forcing their breast works at the muzzle of their guns, and obliging them to ground their arms and surrender at discretion, so that the victory on our part was complete. We took two pieces of brass cannon, and a number of prisoners, baggage, &c. This was no sooner accomplished than Col. Breyman, with one thousand German troops, arrived with two field pieces, to reinforce Col. Baum, who had just been defeated. Gen. Stark's troops were now scattered, some attending the wounded, some guarding the prisoners, and still more in pursuit of plunder—and all exhausted by extreme hunger and fatigue. At this critical moment Col. Warner's regiment arrived and the other troops being rallied the whole was ordered to advance.—A field piece had been taken from Baum in the forenoon and Stark ordered it to be drawn to the scene of action, but his men having never seen a cannon knew not how to load it, the General dismounted and taught them by loading it himself. An action soon commenced, and proved warm and desperate, in which both sides displayed the most daring bravery, till night approached when the enemy yielded a second time in one day to their yankee conquerors. The German troops being totally routed, availed themselves of the darkness to effect their retreat. The whole number of killed, wounded and prisoners, was nine hundred and thirty-four, including one hundred and fifty-seven Tories—of this number, six hundred and fifty-four are prisoners. Col. Baum received a mortal wound, of which he died. Besides the above, one thousand stand of arms, four brass field pieces, two hundred and fifty dragon swords, eight loads of baggage, and twenty horses fell into our hands. The loss on our side, was not more than one hundred in the whole."

ANECDOTE.—Selected from Thacher's Journal.

"General Washington seldom smiles; I never saw him laugh but once; it was after the preliminaries of peace were signed, and at a Yankee story told by Dr. Thomas. There is not, perhaps, another man who can boast of exciting laughter in general Washington."

This is a mistake. Another gentleman who was often near his person during the revolutionary war, in important public functions, and who was then and is, one of the greatest wits of the age, excited him to laughter, almost at will, and that by original pleasantry much superior to the ancient story of Dr. Thomas.

The adieu between General Washington and the principal officers of the army, who met at a tavern, to take a final leave of him after the war, exhibits him in a mood that exalts his character as much as the grave equanimity which

he displayed in battle and in the midst of the most complicated difficulties and dangers.

"Filling a glass; he turned to the officers and said—'With a heart full of love and gratitude I now take leave of you. I most devoutly wish that your latter days may be as prosperous and happy as your former ones have been glorious and honorable.' Having drank he added—'I cannot go to each of you to take my leave, but shall be obliged to you if each of you, will come and take me by the hand.'—General Knox being nearest, turned to him. Incapable of utterance, Washington, in tears, grasped his hand, embraced and kissed him. In the same affectionate manner, he took leave of each succeeding officer. In every eye was the tear of sensibility, and not a word was articulated to interrupt the tenderness of the scene."

PATRICK HENRY.

When Patrick Henry, who gave the first impulse to the ball of the American revolution, introduced his celebrated resolution on the stamp act into the House of Burgesses of Virginia (May 1765,) he exclaimed, when descending on the tyranny of the obnoxious act, "Cesar has his Brutus; Charles the First his Cromwell and George the III!"—"Treason!" cried the speaker; "treason, treason!" echoed from every part of the house.—It was one of those trying moments which are decisive of character. Henry faltered not for an instant; but fixing on the speaker an eye flashing with fire continued, "may profit by their example. If this be treason make the most of it."

Percy Anecdotes.

A man without money is a body without a soul—a walking death—a spectre that frighter every one. His countenance is sorrowful, and his conversation languishing and tedious. If he calls upon an acquaintance he never finds him at home, and if he opens his mouth to speak, he is interrupted every moment, so that he may not have a chance to finish his discourse; which, if feared, will end with his asking for money. He is avoided like a person infected with disease, and is regarded as an incumbrance to the earth. Want wakes him up in the morning, and misery accompanies him to his bed at night.—The ladies discover that he is an awkward boob—landlords believe that he lives upon air, and if he wants any thing of a tradesman, he is asked for cash before delivery.

A Repartee.—While Napoleon was yet a subaltern in the army, a Russian officer with much self-sufficiency remarked, "that his country fought for glory, and the French for gain."—"You are perfectly right," answered Napoleon, "for every one fights for that which he does not possess."

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscribing, will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrearages are paid.

Agents who procure seven subscribers, and become responsible for the payment, will be entitled to copy gratis, and in the same proportion for a larger number.

(Concluded from page 34.)

in preparing your seed wheat the first thing attended to is to clear it perfectly from every injurious foreign substance. "One error may mar our whole system, and render it skill productive of as much evil as good. A poor and worn out land the evil of sowing a mixture of impure seed, with grain or grass, would be great—but where the ground is high order, the crop is more injured; thexious plants take firmer hold, and are more difficult to be eradicated."* Indeed, it would be better for a farmer to pick over his seed at by single handfuls, and make a riddle of fingers, than to sow cockle, darnel, tares, turnip seeds, and other vegetable nuisances, which are as intrusive as unwelcome, as noxious of life as they are unworthy of excuse. The first preparation therefore should be to screen, winnow and riddle the grain till it is perfectly freed from these and other improper ingredients. When this is thoroughly accomplished, washing and steeping, for the purpose of preventing smut, should meet attention. The next step in the processes to be instituted against smut, as recommended by Sir John Sinclair, is to run the grain *very gently* through a riddle, so as not only to clear the grain of the smut balls, but the imperfections and the seeds of weeds will float, and can be skimmed off at pleasure." The same author enumerates as modes by which smut may be prevented, 1. The use of pure clover and lime. 2 Boiling water and lime. 3. Water impregnated with salt. 4. Urine pickle. 5. A solution of wood ashes. 6. A solution of arsenic. 7. A solution of blue vitriol. It seems that almost any acid, corrosive or poisonous application will secure a clean crop, if properly used, and at purpose.

Arthur Young sowed fourteen beds with same wheat seed, which was black with smut. The first bed was sown with this wheat without washing and had 377 smutty kernels. The second bed was sown with seed washed in clean water and had 325 smutty kernels.—Washed in lime water 43 do.—Washed in a lie of wood ashes 43 do.—Washed in arsenic and salt mixture 23 do.—Steeped in lime water four hours 2 do.—Steeped in lie four hours 3 do.—Steeped in arsenic four hours 1 do. Again, that which was washed in lie, as before mentioned, twelve hours had none; and that which was steeped in the same kind of lie twenty-four hours, had none; and that also which was steeped twenty-four hours in lime water, had none; that steeped in arsenic twenty-four hours had 5.

a communication by O. Fiske, Esq. New Eng-
mer, vol. i, page 222.

We shall now speak of the liability of wheat to become winter killed. The author of *Letters of Agricola* states as an objection to the cultivation of wheat in Nova Scotia, "its liability to be thrown out in the spring, and thus subjecting the farmer to serious inconvenience and often disappointment of a crop. Grasses are not exempt from the same hazard; and the hopes of the year are thus blighted by a cause, which, in many cases, will admit of remedy, in full alleviation. I am not sure but sowing the wheat seed under furrow at least four or five inches deep in September, in order that it may extend its roots and take a firm hold of the soil before the approach of winter, and rolling it in the spring with the box heavily loaded would obviate the evils of our climate, and enable us to cultivate that grain according to the improved modes of England. It ought to be recollected that even there, about sixty years ago, winter wheat was not of general cultivation, and the heaving of the soil was accounted a powerful obstacle to its success. In Scotland, too, during the same period, spring wheat almost universally prevailed; and her northern and bleak position was thought to be incapable of any change to the better, and utterly unfriendly to autumnal sown. The zeal and industry of British farmers, combined with their skill, have baffled all these gloomy predictions, and taught us at once to copy the example of our sire, and not to despair in the race of improvement."

A method, according to the same author, made use of in Norfolk, Eng. to guard wheat against the changes and inclemency of winter and spring, is to adopt the following rotation. "After a turnip crop, they sow barley the second year with clover seeds; the third year they cut hay, and plough down the ley, and sow their winter wheat on the matted sod. The roots of the grass bind the soil, and prevent it from heaving, which is much akin to the same effect produced by the tangled and bound surface of our new and cleared lands." This fact may suggest another inducement to

* See *New England Farmer*, vol. i, page 275.

It is well known that our lands, where the soil is at all suitable, will produce good crops of wheat when first cleared from their native growth of wood; but after having been tilled for some years, they generally yield wheat with difficulty, and it is often found impossible to raise it by any of the modes commonly adopted for wheat culture. In most parts of Massachusetts, and in some parts of New Hampshire and Vermont, the farmers scarcely ever attempt to raise wheat, and still more rarely succeed when they do attempt it. Yet, we believe wheat was a common and profitable crop in those places in the early period of their settlement. In process of time, however, the land became exhausted of its wheat-bearing faculty, and our farmers were forced nearly to forego its cultivation. The same variations and appearances have likewise been observed in Europe. Wheat countries, by continued cultivation, have become almost incapable of yielding wheat. The cause and remedy of this partial barrenness, this falling off, with regard to particular plants, was alike involved in obscurity, till modern discoveries in chemistry threw light on the subject. It has been found that the texture of every soil is defective unless there is a mixture of three kinds of earth, viz. clay, sand, and lime; and that lime, in some of its combinations, exists in wheat both in the straw and kernel. In some soils, fertile in other respects, lime may either have no existence, or be found in very minute portions, and be soon exhausted. If lime be a necessary constituent of wheat, and is not in the soil where we attempt to raise wheat, it must be supplied by art, or wheat will not grow. Or if native lime exists in the soil, in small quantities, the land may bear wheat till the lime is exhausted, and then become incapable of producing that plant, till a fresh supply of lime, marle, pulverized bones, or some other calcareous substance is added.—

Mr. Young says, (Letters of Agricola, p. 293,) "it cannot be denied, that since the plentiful use of lime has been adopted, lands in Europe will produce wheat which otherwise were incapable of bearing it, and quotes several instances in proof of this assertion. Dr. Anderson likewise gives an account of a field, which had a top dressing of lime for the purpose of raising wheat, but the lime, by accident, was not applied to a small patch of the field, and in that patch there was no crop, while every part of the field to which the lime was applied produced wheat luxuriantly. It would be easy to adduce many more instances to prove that lime in Great Britain is considered not only useful but indispensable for the production of wheat. A British farmer, we believe, rarely undertakes to raise wheat *without* the use of lime, and an American farmer as rarely undertakes to raise it *with* the use of that substance for manure.

If the foregoing premises are correct it would seem not impossible, and indeed scarcely improbable, that by the judicious use of lime, or other calcarious substances, wheat may be as well raised in New England as in the Western

States. The subject is certainly of very great importance, and deserves repeated experiments.

It will be objected against the use of lime, 1st, that it is too dear to be used for manure, and 2dly, that our farmers do not know how to apply it, and as it is a powerful substance it may do more hurt than good, unless in the hands of a chemist, or one practically acquainted with its operation. With regard to the dearth of lime, we are informed that there is no want of lime-stone in almost every part of the United States; and probably, by proper search, many more lime-stone quarries might be discovered in New England than are at present known. And the price of lime would doubtless be diminished by increasing the demand, because if great quantities were wanted for agricultural purposes, a greater number of persons would find their account in making a business of manufacturing it; improvements would be introduced in the processes connected with its manufacture, and of course it would be afforded cheaper. Besides, small quantities would alone be needed for the purpose of furnishing that calcareous matter which nature inclines to incorporate into the substance of wheat, clover, &c., and probably a top dressing of two or three bushels to the acre would be of essential benefit, though doubtless more would, generally, be preferable. Mr. Young says a small quantity of quick lime scattered on the surface of land newly cleared, will prove highly beneficial during the whole length of time they remain untilled. Thirty bushels of shells [lime fresh from the kiln] to the acre, slacked into a fine powder, will produce the most surprising effects, if not on the first crop of wheat, at all events on the verdure, luxuriance, and quality of the future pasture.* A writer in the *Museum Rusticum*, an English work, says "that he sows his wheat without laying on any manure, but early in the spring gives a top dressing of twenty bushels of lime, pulverized, and mixed intimately with forty bushels of sand, and if the weather be dry, he doubles the quantity of sand." We are disposed to believe that at least lime enough for light top dressings might be easily procured by almost every cultivator in the Union. And such light dressings, if our theory is correct, would be all that is *indispensable* to the production of wheat.

With regard to the mode of applying lime, nothing can be more simple. It should be evenly spread, after being water slacked, on the surface of the soil, and not ploughed in, or if ploughed in it should be with a very shallow furrow, because its tendency is to sink below the reach of cultivation. If used in a quick or burning state it will be safest to mix it with about double its quantity of sand, loam, clay, or some other material. The additional material may be made to correspond with the wants of the soil to which it is applied. Thus, if the soil has too much clay, mix sand with your lime. If too much sand mix finely pulverized clay, &c.

It is said that British farmers apply lime in great quantities directly from the kiln in its most caustic state, even to land which is replete with putrescent or vegetable manure, and run the risk of consuming or wasting the manure by its corrosive qualities. But the soil of G. Britain is generally wetter than ours, and of

course the lime sooner becomes mild. Besides, there is a great difference in the strength of lime, and that of the United States may be, generally speaking, stronger than the English lime. In short, we should advise every farmer to use quick lime as manure, in small quantities at first, mixed with a large proportion of earth, or some other substance to *dilute it*, and thus take care not to burn his seed, his fingers, or his growing vegetables. And with these precautions we would make use of it for wheat as a *top dressing in spring*. We would likewise try it mixed with wood ashes, together with earth, for we have been told by a practical farmer that ashes and lime form a union much more valuable than either separate.

We will now close our remarks with but one further observation. The only use of burning lime at all for manure is to make it easier to reduce it to a very fine powder. It supplies no food for vegetables while in its quick or caustic state. Pounded lime-stones, the plaster of old walls, &c. if made fine enough, are quite as efficacious as fresh lime, in proportion to the carbonate of lime, or lumpy substance they contain.

FOR THE NEW ENGLAND FARMER.

BLIGHT ON PEAR TREES,

With a notice of an article on the same subject in the Northampton Gazette.

For twenty years past pear trees throughout the United States have been subject, in mid-summer, to a disease of a very extraordinary nature. Sometimes one limb, sometimes nearly the whole tree, has appeared, with all its fruit standing, to perish in forty-eight hours without any apparent cause. Gardeners called it "fire blight," and attributed it to lightning, but as no violence appeared upon the tree, as none of these terrific effects were perceived, which always accompany that powerful and destructive, though probably highly useful instrument of nature, I was led to doubt whether electricity had any share in the mischief. I was pleased to see that some gentleman in Northampton had adopted Professor Peck's solution, because it proved, that scientific researches, though not immediately noticed, are ultimately useful.

As the pear tree is very valuable, and in all its varieties furnishes most delicious fruit from July to May, I think it a duty to state the history of the discovery made by Professor Peck, and the certainty of success which must follow the adoption of his; I will not call it theory, but discovery. My neighbors had long been afflicted by this scourge. I had been fortunately exempt from it. At last one of my most healthy and valuable trees was attacked—nearly half the tree perished in a night. I could perceive no violence, no symptom of electric force. I was convinced that it was the effect of some internal enemy. I instantly sawed off all the limbs affected, and proceeded to examine them. I found at last the enemy, not at the point where death ensued, but some inches below it. The insect was very small, apparently incapable of such extensive mischief, but the effect was certain, and the manner of producing that effect was obvious. It had eaten a complete circle of the alburnum or sap-wood not exceeding the size of a knitting needle, so as completely to intercept the passage of the sap. I found the

insect in three different limbs, and not in the larva but the perfect state. It was not however prepared in point of strength to issue forth and by its eggs to deposit the means of new depredations. I carried it over to Professor Peck, and hence arose his account of the insect which proved to be of the race of wood eaters though a new and undescribed one. The most important fact however is, and it is by *fact* alone that gardeners and farmers must be governed, that by steadily pursuing the system of cutting off the limb many inches below the apparent injury and burning it, I have extirpated it from my estate. A FARMER.

Rosbury, Sept. 1823.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—Within a few years I have devoted some time and attention to the cultivation of an orchard. If I am correct in my view of the subject, a good orchard is the most valuable part of a farm, and the farmer who neglects to cultivate one may with propriety be said to neglect an important branch of good husbandry.

Five years ago I selected a piece of land to be devoted exclusively to an orchard. It had naturally a good soil, and descends a little to the east. It was somewhat rocky; many of the rocks being so large and heavy as to render necessary to blow them in order to remove them. I cleared the rocks all off so that no one was to be seen on the piece above the surface of the ground. I enclosed this piece of ground with a substantial stone wall, and then ploughed and planted it with potatoes. After digging the potatoes, I again ploughed and harrowed it, then marked out the rows for the trees, being very careful to have them exact straight each way. I then dug the holes for the trees, making them four feet in diameter and 12 or 15 inches in depth, taking care to lay the top and bottom of what I took out each by itself. About the first of November I set out my trees, being careful in taking them to injure the roots as little as possible. In each hole, after placing the roots of the tree, I put three pecks of compost manure next to the earth taken from the top of the holes, leaving that which was taken from the bottom to be placed on the top. On this piece of ground I set one hundred and thirty trees, having the exactly twenty feet distant from each other. The spring after setting the trees I planted the ground with corn, and the next spring sowed with wheat, seeded it down to grass, and grazed the trees. The grafts grew rapidly the first years after they were put in. I then put half a bushel of manure around each tree, and they still continue to flourish, the largest of them being six inches in circumference. I have lately ploughed the ground, and intend next spring to plant it with potatoes in order to better their growth.

The probability now is that in the course of five years more, my orchard will be quite productive, should it continue to flourish. The farmer who has not a young orchard coming would do well immediately to choose a piece of ground, and after thoroughly preparing it, to plant it out with apple trees.

No one ought to be afraid of devoting too much time or attention to an orchard, for if rightly managed it will, after a few years, and

* Letters of Agricola.

repay all the trouble and expense. An orchard set in ground that has once been ploughed will not flourish unless it be ploughed every year or three years. Perhaps it is the better way to keep it in tillage the whole time, as the trees will certainly grow much faster, and produce more and better fruit. Beauty and order are desirable in an orchard as well as in other things. How much more pleasing it is to see them stand in regular order, the trees being set in rows perfectly straight each way, than to see them stand here and there in a promiscuous manner like the trees of a forest.

Much care should be taken during the first year of an orchard to give the trees a regular proper shape. This must be done principally by pruning. Branches should not be permitted to come out from the body of the tree at a less distance than five or six feet from the trunk. Cattle, sheep nor hogs should never be turned into a young orchard, as they will easily injure the trees by rubbing against and gnawing them. A FARMER.

Worcester, August, 1823.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—It is well known that Intemperance has become a great and growing evil in our country, and it highly concerns every friend of humanity and social happiness to make every exertion in his power to arrest its progress. Many of our citizens have ruined themselves and their families and become a burden to society by a constant and too free use of ardent spirit. Many others are pursuing the same course, and will meet the same fate. The drunkard does not become such all at once; he is first a temperate man, then drinks pretty freely, and before he is aware becomes a toper. It is very easy to get into the way of using strong drink, and every person ought to be cautious how he indulges in habits of this kind, lest he eventually be carried down with the current. It has become a practice with most of our farmers to make a constant use of ardent spirit, particularly during the season of getting hay and grain. Many seem to imagine that it is as necessary, at this time, as their daily food. I have formerly pursued this course, and considered it necessary to drink rum three times a day, as to take food at the stated seasons. But I have learned from actual experience that this practice is not only unnecessary, but altogether more than useless. For four years I have entirely dispensed with this habit. I feel much stronger, and can endure the heat and labor of the day better than formerly. When I used to take my morning dram and go out to mowing, I was enlivened for a little while, but soon my strength began to fail, and before breakfast I became quite exhausted. The same course produced the same effect at other times in the day. Now my practice is to drink a glass of milk and water in the morning before I go to mowing, and I stand it well an hour and a half or two hours, then I can eat my breakfast with a good appetite, and work till noon without being much fatigued. After dinner I work till five o'clock, then I take supper instead of a glass of toddy, and can work the remainder of the day, and sleep well during the night.

Two of my neighbors, who occupy large farms, have adopted the same course, and are

fully convinced of the utility of it. They too, have demonstrated, by fair experiment, that more work can be performed without rum than with it. If our farmers generally would adopt this method, there can be but very little doubt that they would be convinced that it is far preferable to the prevailing custom of the time. W.

TO THE FARMERS OF ESSEX.

The Trustees of the Essex Agricultural Society offer the following Premiums, to be paid in the autumn of 1824:

For the management of a farm in its tillage, mowing, orcharding and pasturage; the quantity of land appropriated to each—the means and the manner of making, increasing, preserving and applying manures—their quantities—the respective crops and products—the quantity and management of the live stock—and the quantity of labor employed, to be detailed.

For the best,	thirty dollars.
For the 2d best,	twenty five dollars.
For the 3d best,	twenty dollars.
For the 4th best,	fifteen dollars.

In addition to the above, the Trustees of the Massachusetts Agricultural Society have offered a premium of thirty dollars, to be paid to the successful claimant of the first premium for the best management of a farm offered by any County Society: so that the first premium offered for the best management of a farm in this county, is now sixty dollars.

Persons intending to claim these premiums, will take notice that all claims for them must be entered with the Secretary of the Society on or before the seventh day of May, 1824.

The Committee of examination will view each of the farms that may be entered for premium, in the fourth week in June, and the first week in September; commencing this service on Monday each week. They will require each claimant to furnish them with a statement of the produce of his farm in 1823, as particular as may be practicable; and also an accurate statement of the produce of his farm in 1824. These written statements of produce, mode of cultivation, &c. together with satisfactory evidence of their correctness, must be handed to the Secretary of the Society, on or before the 20th of November, 1824, at which time they will be examined and the premiums will be awarded.

For further information respecting premiums offered and subjects for premiums, the Trustees refer to their pamphlet published in January, 1823; and they would remark generally, that all the premiums there offered, for which no particular time of payment is mentioned, will be paid in 1824, if claims sufficiently meritorious shall be presented.

Published by order of the Trustees.

J. W. PROCTOR, Sec'y.

September 2d, 1823.

The following information (says the N. Haven Herald) may not be uninteresting to the farmer.

It is customary, in many places, to use a thin piece of board with a short handle—the blade covered with sand, or some other substance, for the purpose of sharpening scythes in the field. It is commonly called a *rifle*. Take your rifle, if you have one, and scrape off the sand—grease it well, and then rub on it a small quantity of

the white Oxide of Tin, commonly called Flour of Putty. An ounce of it may be had at the druggist's for a small sum; and it is believed to be the best substance for scythes that has yet been discovered.

It is frequently made from the dross of a mixture of block tin and lead, and may generally be had of the pewterers. It has been used in some parts of the country, 10 or 50 years, for similar purposes; but the fact is not generally known.

BLEACHING LINEN.

We understand that a very great improvement in the method of bleaching linen and yarn has lately been made by Mr. Crookshank, of Dublin. As far as we have been able to ascertain its chief merit consists in the disengaging the chlorine from the oxy-muriate of lime—by which ingenious process it is enabled to act with its full force on the cloth and yarn. Independently of a considerable saving in the quantity of the bleaching liquor, by which the possibility of injuring the linen is prevented, this process combines some other very important advantages. It has already been tried on a considerable scale, and has met with the fullest approbation of a gentleman of chemical celebrity. We are informed that Mr. Crookshank has submitted his discovery to the Linen Board, and proposed to exhibit its advantages by a course of experiments.—*Dublin paper.*

From the Maine Intelligencer.

METEORIC STONE.

Mr. Dorr—As some account of a *Meteoric Stone* which lately fell in Nobleboro', may be interesting to many of your readers, I send you the following, as related by Mr. Asa Dinmore, a very intelligent farmer by whom it was found.

As he was at work in his field, between 4 and 5 o'clock, P. M. on the 7th of August, his attention was arrested by an unusual noise in the sky directly over his head, like the firing of many guns in repeated succession, and as loud as the report of a musket at the distance of 20 rods. This noise continued four or five minutes, the succession of the reports growing more rapid until the whole sounded like the roll of a drum. About five minutes after this sound had ceased, he heard something like the noise produced by the wind among the trees, and looking up to discover the cause, saw what he thought a cloud in quick motion, and at that instant heard something strike the ground near him. He proceeded to the spot, and found that about six rods from where he had been standing a stone had entered the earth to the depth of six inches, when striking another stone it broke in pieces. He thinks the stone would have weighed as much as four pounds. The stone is of an *ashy gray* color, covered with a coat of black resembling *oxide of iron*. Its granular texture resembles coarse sand-stone.

Receipts to cure Warts.—Take the inner rind of a lemon, steep it four-and-twenty hours in distilled vinegar, and apply it to the warts. It must not be left on the part above three hours at a time, and is to be applied afresh every day. Or divide a red onion, and rub the warts well with it, or anoint them with the milky juice of the herb mercury several times, and they will gradually waste away.

From the Massachusetts Agricultural Repository.

ESSAYS ON FLAX HUSBANDRY.

BY S. W. POMEROY, ESQ.

First Vice President of the Massachusetts Society for Promoting Agriculture.

No. III.

SOWING.

The seed should be got in as early as it is possible to prepare the ground. Dr. Deane observes that a slight frost after the plants are up will not injure them. For no crop is it more important that the seed should be equally distributed. Fortunately what has long been a desideratum is now attained. A machine for sowing small seeds broad cast, with perfect regularity, great expedition, and in any desired quantity, has lately been invented, and performs to great satisfaction.*

WEEDING.

Weeding is considered in Europe, and by good husbandmen in this country, as necessary to secure a good crop of flax, which is a very tender plant when young, and more easily checked in its progress by weeds than any other. It is not supposed to be injured by the clover and grass sown with it: on the contrary the Flemish farmers think them beneficial, by protecting the tender roots from drought, and keeping the weeds under. It should be carefully weeded when the plants are three or four inches high: they are not then injured by the laborer going barefooted over them.

PULLING.

This should be performed as soon as the leaves begin to fall, and the stalks shew a bright yellow color, and when the bolls are turned a little brown. The seed will continue to ripen afterwards. When the flax is lodged it should be pulled immediately, in any stage of its growth, or it will be entirely lost; great care is requisite in sorting the different lengths, and keeping them separate till after the flax is backed, or much waste will ensue in that process.

SAVING SEED.

As soon as the flax is dry enough to put under cover, the bolls should be ripped, as it is termed. A comb resembling the head of a rake, but with teeth longer and nearer together, made of hickory or oak, is fastened upon a block, and the flax, taken in parcels no larger than the hands can firmly grasp, is drawn through, and the bolls ripped off; attention to sorting at the same time should be continued. The bolls are to be riddled and winnowed immediately; spread thin on a clean floor, or on sheets, in the sun, and when sufficiently dry, and beginning to open, threshed. By this method the foul seeds are completely separated with little trouble, and good, clean seed is ready for an early market, often the best, without the use of expensive machinery to make it so. Here the operations of the farmer ought to end! The process or preparation being foreign to, and unconnected with his other pursuits; and which has been the greatest objection to extensive flax culture.—

* Bennett's machine for sowing broad cast, a description and drawing of which are given in the Memoirs of the Philadelphia Agricultural Society, vol. 4, with ample testimony of its usefulness. It is pushed forward by a man, like a wheelbarrow, and will sow more than one acre in an hour, unimpeded by wind or light rain.

Can there be any reason why the farmer is to prepare his flax more than the hides of his cattle which he sends to the tanner? They are both chemical processes; and to dissolve the glutinous or resinous substances by which the fibres are attached to the stem, without impairing their strength, is perhaps as critical, and requires as much care and judgment, as to extract the animal juices from the hides, and fill the pores with tannin! In short, the flax grower and flax preparer and dresser, should be distinct professions. They are said to be so in Flanders and Holland, and were extensively so in Scotland, where the farmer sold his flax on the ground, or in sheaves at his barn or rick.

The preparation of flax by steeping is very general in the great flax growing countries in Europe, but it is not quite finished in the water. It remains spread some days on the grass, which is necessary to render it soft and give that silvery appearance so desirable. The destructive process of dew rotting, is most commonly practised in this country, and when water is resorted to, it is at an improper season, and the process imperfect; which is the cause of its being so harsh and brittle. Perhaps no part of the system requires such an allowance for difference of climate. In the humid atmosphere of Ireland, it is not very material when it is spread; but in this climate, when exposed to a July or August sun, every drop after a shower, becomes a burning-glass, and literally scorches the fibres; besides, such a highly putrid fermentation as will then take place in the water, though it separates the harle more speedily, not only injures it, but communicates a stain that renders the process of bleaching much more tedious and expensive.

The flax should not be put into the water till about the first of October, and remain from ten to fourteen days, according to the temperature of the weather, and should be taken out before the fibres will separate freely, spread on the grass, when the frost will very much assist the operation, and the flax exhibits a gloss and softness that it is impossible to give it otherwise.

The following method of preparing hemp, will apply with great force to the point under discussion. During the late war, an experienced ship-master in Connecticut, and who was also a good farmer, raised a crop of Hemp. As soon as it was dry enough to be stowed away, it was put under cover, and remained till October; was then put into clear, soft water, till the fibres would separate with some difficulty, when it was spread on the grass; the frost completed the operation, and when dry it was immediately secured. There was no putrid fermentation to deteriorate the harle, nor was it mellowed by being exposed to the weather, and when dressed, exhibited that fine silver green hue by which the best Russian hemp is distinguished; and when worked up, was pronounced by the rope-makers to be equal to any hemp ever imported! Here is a lesson for our western brethren that is worth more to them than real mines of silver. Clear, soft, stagnant water is preferred in Europe. A canal, forty feet long, six broad, and four deep, is said to

* The best *Riga Hemp*, supplied for the British Navy, is prepared by steeping, during which it is shifted three times.

be sufficient for the purpose of an acre of flax at one time. It should be formed on a clay, or some holding soil, where the water from a spring or brook can be conducted in with convenience; the expense would not be great, and on most farms suitable sites may be had. May not boiling or steaming be found the most advantageous process of preparing flax? The very superior sample of thread exhibited at Brighton, in 1817, for which Mrs. Crowninshield, of Danvers, received a premium, was spun from flax prepared by boiling! It appears by the "transactions of the Swedish Academy," that a method was practised in Sweden of preparing flax to resemble cotton, by boiling it ten hours in salt water, spreading on the grass, and frequently watering, by which it becomes soft and bleached. Boiling or steaming will not appear very formidable or expensive when we examine the subject. A box twenty feet long, six feet wide, and four deep, well constructed with stout plank, a boiler, from which a large tube extends into and communicates with the water in the box, will boil the produce of a quarter of an acre in a day, that is, if we allow double the room to boil in that is required for steeping. A steam pipe, instead of the tube, and having the top of the box well secured, would permit the process of steaming to go on. It is probable that by either method, grassing will be necessary to obtain soft flax. The yarns of which the sail cloth is made at Puterson, are all steamed.—The navy board expressly forbid their being boiled in alkaline lye, as is usual in most manufactures of linen. It is from this precaution that their canvass has the pliable, oily feeling which so much recommends it. It should not be lost sight of, that by boiling or steaming much time and expense will be saved in bleaching.

We arrive at the final process, Dressing, and in this our climate gives a decided advantage over Ireland, Flanders, or the north of Europe, where the flax is dried on hurdles, over a peat fire, in ovens, or kilns, requiring great care in regulating the heat, to prevent injury. All this trouble and hazard is obviated by our dry atmosphere and keen north-west winds.—Dr. Deane estimated the expense of dressing flax by hand at one third the product. I believe the present price does not much vary from his estimate. A respectable gentleman from Dutchess county, New York, informed me, that mills or machines, impelled by water, have been erected there, that break and completely dress the flax for a toll of one tenth! It is said that one or more of them are in operation in the western part of this state. These mills were invented in Scotland, and are now said to be brought to great perfection. They are erected in all directions in the principal flax districts in Ireland, and notwithstanding the low price and limited demand for labor, are resorted to by the poorer classes of people, the dressing by hand being mostly abandoned. There are machines in England that dress the flax immediately from the field, without any preparation whatever. An account of them may be found in the 5th vol. of the Massachusetts Agricultural Journal. It appears, by the report of a committee of the House of Commons, that in 1817 they were in successful operation. A man and three children impelled the machines and dressed sixty pounds a day. We have no information of any further improvements.—

ould they be susceptible of the application of water or steam power, in any degree proportionate, the advantages may be incalculable. In the present inquiry, we place these matters, however desirable, entirely out of the question.

PRODUCT.

is not uncommon in Great Britain and Ireland to obtain eight hundred pounds of flax from an acre! Six hundred pounds is estimated, in some districts, as an average; but it should be observed, that little, if any, seed is obtained. The average crop in New England, as far as our information extends, cannot be estimated at more than two hundred pounds, and six or eight bushels of seed. (We do not include the rich portions on the Connecticut, and some other rivers.) Dr. Deane was of opinion that four hundred pounds might be calculated on with proper management.

One might think that four hundred pounds of good flax, from flax, and eight or ten bushels of seed, is fairly assumed as a medium crop on favorable soils, where the culture becomes such an object as to make other farming operations convenient to it, and due attention is paid to the change of seed.

Those who grow flax to any extent are of opinion, that the seed, at the price it has been some years past, pays for all the labor before and on the crop to the time the flax is ready to be prepared or rotted.

As we are correctly informed, flax of a fair quality cannot be imported from Ireland for less than fourteen cents per pound. And the seed of the best of Russia flax delivered on board at St. Petersburg, is ten and a half cents per pound. The quality called "twelve deniers" costs nine and an half cents on board. The quality of flax raised in this country varies more than any other product; and of course the price, which is from six to eighteen cents; the medium about ten cents per pound.

It must be acknowledged, that no great exertion can be expected in the pursuits of any people, unless the prospect of reward sweetens their labors.

And I anticipate the question that some are disposed to ask, before they have finished perusal of these essays, "where is the market to find a market, if flax is extensively raised?" We will ask where could the planter have found a market for his cotton if machinery had not been invented for spinning it? How could he have supplied it, if the labor of thousands of hands had been required to spin the seeds, that is now performed by the Cotton Gin invented by Whitney? We have heard that the expense of dressing flax has been reduced from one third to one tenth of its value.

It is a fact well established, that there are in the country, machines for spinning flax, to perform as well, and more expeditiously, than for the finer threads, than those for spinning cotton! The Paterson sail cloth is fabricated from yarns spun and twisted by machinery, assisted by as little manual labor as cotton machines. In those manufactories are six hundred spindles. In the state of New York, Pennsylvania about three hundred more employed for sewing thread, sheeting, bed-cloth, twine, &c. The expense of retting the flax is halcked, in attending a

usual toll for ginning Cotton in Alabama, we are told, is one twelfth.

machine of twenty-four spindles for spinning common shoe thread, is thirty-three cents per day, spinning on an average twenty-four pounds a day, or one pound a day for each spindle! equal, as it is said, to the production of a cotton spindle for five or six days!

Can any thing be wanting but the application of power looms for weaving linen, to place the manufacture nearly upon an equality with cotton? And is there any doubt but they can be so applied?

The perfection of cotton spinning machinery, and the invention of power looms, with such improvements as are exhibited at Waltham, it is well known are about to produce an entire revolution in the India trade! If they can stop the spindle and the shuttle of the Hindoo, who is supported upon a handful of rice a day in a climate where little is required for clothing or shelter, what must be the effect of corresponding machines in the linen manufacture, upon the Russian and the German? There is probably at this moment, a million tons of American shipping clothed with Russian canvass! What, but the raw material of good quality, is required to elicit Capital, to manufacture in a few years even to compete with European nations in the linen market?

The exportation of linen from Germany to North and South America has been and is at present, of vast amount! The single province of Silesia has sent in one year to Hamburg and other ports, linens to the value of nearly five millions of dollars to be shipped by the circuitous route of Cadiz, to the Spanish colonies. These customers are at our doors. The United States possess the "Golden Gates of this Commerce," and with exertions well directed to her agriculture, Europe will be obliged to surrender the keys.

From the Old Colony Memorial.

No branch of science, perhaps, more deeply interests the practical farmer and frugal, than Entomology. It is an object of the first importance to investigate the natural history of those insects which are peculiarly injurious to us in any way; and perhaps no country on the earth more abounds with such insects than our own; yet their history has hitherto excited but little attention. The last year was remarkable in this place, (and more or less thro' the county) for the devastation made by the grub-worm on almost every green thing. The fact was noticed in your paper at the time, and the patriotism of the Roxbury Farmer, "ever tremblingly alive" to the interests of our agriculture, impelled him to invite information of the kind of insect capable of making such extensive devastation." A description of the grub worm was given, so far as facts could then support it, with a pledge to observe its progress, its habits of life, and if practicable its metamorphosis, which was then assumed as a matter of course.

With these views, on the approach of cold weather, viz. on the 13th of October, I put six of them into a box with earth, and had them placed in the cellar secure from frost. On the 30th October, on examining those in the fields, I found they had buried themselves deeper in the earth, say four or five inches. On the 12th November, and again the 21st December, in ploughing those fields which had before been

eaten by them, many were turned up by the plough, at five or six inches deep; and in other places they are said to be found in all depths, from six inches to three feet. The greatest depth at which I have at any time found any, was about 13 inches, in digging a hole to set a post; from these, and many other inspections, I could never find any that had assumed the chrysalis state, but were found at all sizes, from half an inch, to one and half inch long in the grub.

Those I put into the cellar, I occasionally watered to keep them from perishing, and in April had them brought into the open air, and on examination could observe no visible change. They were then placed in the garden, and the box covered with a sod to afford them food, and were inspected weekly, without perceiving any alteration, except wasting, until the 15th of July, when finding two of the number dead, I gave liberty to the others. Thus my anticipation of observing their metamorphosis was disappointed.

In connexion with the subject I will state another observation made in July. Having occasion to move some manure from the barn to prepare a piece of ground for raising the round or English turnip, I found an unusual number of the large white worm, (such as are generally found in similar situations, and are considered harmless.) I was induced to subject several of them to an examination through the microscope, and found them perfectly similar to this grub, in all points, the number of the *incisors* and *spracles* the same, the position and number of the legs and antennae corresponding, and no perceptible difference except they might possibly be a little larger, or certainly of the largest size, and were also infested with a *parasitical animalcula*, in appearance through the microscope resembling the turnip fly, but invisible to the naked eye. Now these from their situations must be a progeny of annual growth, for the manure, in which they were recumbent, was the collection of the preceding winter and spring.

The larva of the cock-chaffer, so analogous to the grub-worm under consideration, is ascertained to continue in its larva state four years, before it assumes the chrysalis; and on the fifth it becomes metamorphosed into the *imago* or parent. This is the fifth year since the ravages by this insect where noticed here, and its resemblance to the larva of the cock-chaffer being so striking, its habits and ravages so correspondent, it was assumed to be the same; hence the anticipation, that on selecting some of those that where full grown, and preserving them through the winter, of witnessing their transformation into the *imago*, the beetle probably, from their crustaceous head.

Perhaps it may not be irrelevant to the subject, to conjecture, that the devastation of the three or four last years may be intimately connected with the character of the seasons, which being peculiarly arid, may have driven them to the necessity of seeking moisture from the vegetable creation, to preserve their own existence. The present is a wet season, and although the worms are found to be as numerous in the ground as heretofore, they are perfectly innocuous; no vegetable appearing to be injured from their presence, altho' 13 or 20 are taken in digging one hill of potatoes.

Altho' these facts can throw little or no light on the natural history; the habitudes of life; the character, the change, the metamorphosis, of this insect, I can't but hope they will draw the attention of some one better qualified to pursue the research than

PLYMOUTH.

NEW ENGLAND FARMER.

SATURDAY, SEPTEMBER 6, 1833.

Extracts from a work lately published by WILLIAM COBBETT, entitled "*College Economy*," with occasional remarks on some of the statements of the author.

[Continued from page 39.]

"The man, who is doing well," says Mr. C. "who is in good health, who has a blooming and dutiful and cheerful and happy family about him, and who passes his day of rest among them, is not to be made to believe that he was born to be miserable, and that poverty, the certain reward of laziness, is to secure him a crown of glory. Far be it from me to recommend a disregard of even the outward observances of the ceremonies of religion; but can it be religion to believe that God has made us to be wretched and dejected, and to regard as marks of his grace the poverty and misery that invariably attend our neglect to use the means of obtaining a competence in worldly things? Can it be religion to regard as blessings those things, those very things, which God expressly numbers amongst his curses? Poverty never finds a place amongst the *blessings* promised by God. His blessings are of a directly opposite description; flocks, herds, corn, wine and oil; a smiling land; a rejoicing people; abundance for the body, and gladness of the heart; these are blessings which God promises to the industrious, the sober, the careful, and the upright. Let no man, then, believe, that to be poor and wretched is a mark of God's favor; and let no man remain in that state, if he, by any honest means can rescue himself from it.

"Poverty leads to all sorts of evil consequences. *Want*, horrid want, is the great parent of crime. To have a dutiful family, the father's principle of rule must be *love* and not *fear*. His sway must be gentle, or he will have an unwilling and short-lived obedience. But it is given to few men to be gentle and good humored amidst the various torments attendant on pinching poverty. A competence is, therefore, the first thing to be thought of; it is the foundation of all good in the laborer's dwelling; without it little but misery can be expected. "*Health, peace and competence*," one of the wisest of men regards as the only things needful to men; but the two former are scarcely to be had without the latter. *Competence* is the foundation of happiness and of exertion. Beset with wants, having a mind continually harassed with fears of starvation, who can act with energy, who can calmly think? To provide a *good being* therefore, for himself and family, is the *very first duty* of every man. "Two things," says Agur, "have I asked; deny me them not before I die: remove far from me vanity and lies; give me neither poverty nor riches; feed me with food convenient for me: lest I be full and deny thee; or lest I be poor and steal."

This is an excellent discourse, and worthy the attention of the statesman as well as the

moralist. Poverty causes a people not only to be wretched, but to be wicked. Extreme poverty is not only the mother of misery but the nurse of crime. A man in very straitened circumstances must be almost more than human if he does not become a misanthrope, a man-hater, "fit for treason, stratagem and spoils." He vents his spleen on every sensible object around him, and every living thing that is so unfortunate as to be dependent on him, or within reach of his annoyance, is sure to feel the effect of his savage disposition. Like the arch enemy of mankind he seeks for some alleviation of his own sufferings in causing others to suffer. Poverty is no doubt the chief fomentor of the rebellions and atrocities of the lower orders of the Irish. They feel misery, and wish to inflict what they feel; according to the vulgar but correct adage "misery loves company."—If you see a man beating his horse unreasonably and unmercifully, you may generally conclude that his poverty has at least a share in causing his cruelty. Poverty too is an enemy to economy and a friend to extravagance. The poor man buys dear and sells cheap. He generally buys on trust, and must pay well for the risque the seller runs in trusting him. The poor man sells cheap, because he must raise money to supply his immediate and urgent necessities. He is often extravagant because he is desperate. He sees no prospect of obtaining a comfortable livelihood and maintaining a respectable standing in society, and therefore if he obtains a little money, he throws it away on transient, and perhaps criminal gratifications.—"A dollar or two," he says, "will make no material change for the better in my situation or prospects, and therefore I may as well spend it and take the comfort of it." Such is the suggestion of poverty, not always expressed in words, but often present in the minds of many who are poor, because they are extravagant, and extravagant because they are poor. Judicious precepts and suggestions on rural economy may save persons of this description from the gulf which awaits them if they proceed in their present courses, and may prove highly useful to the rich as well as the poor, by promoting comfort and accommodation, as well as lessening expense.

Mr. Cobbett commences the body of his work with an essay on "Brewing Beer." It seems that family-brewing is not so much practised in Great Britain as formerly, and he tells us that "the drink, which has come to supply the place of beer has, in general, been *tea*. It is notorious," says Mr. C. "that tea has no useful strength in it; that it contains nothing nutritious; that it, besides being good for nothing, has badness in it, because it is well known to produce want of sleep in many cases, and, in all cases, to shake and weaken the nerves. It is, in fact, a weaker kind of laudanum, which enlivens for the moment and deadens afterwards. At any rate it

communicates no strength to the body; it does not, in any degree, assist in affording what labor demands. It is, then, of no use."

Mr. Cobbett's precepts are frequently better than his practical applications of them; as much that he says against tea we think quite erroneous, and much more not applicable to any class of people above the condition of struggling beggars, and paupers supported by the charity of the public. Tea, being a favorite beverage of ours, we shall take arms in its behalf, even against so formidable a champion Mr. Cobbett. We are sure to have the ladies on our side, as well as the more sedate, judicious and temperate part of our own sex.

An English work of high authority says "We have heard much of the bad effects of tea, but we have never felt nor observed them. If it were so pernicious as it has been represented by some, its effects must certainly be evident in China, where it is drunk by all ranks; yet far from being thought hurtful in that country it is held in high estimation. We are told that those who have written the history of China that inflammatory diseases are less frequent there than in many other countries, which are ascribed solely to the liberal use of tea." Let us hear Mr. Cobbett further on this subject.

"It must be evident to every one that the practice of tea-drinking must render the frame feeble, and unfit to encounter hard labor or severe weather, while, as I have shown, it deduces from the means of replenishing the belly the covering of the back. Hence succeeds softness, an effeminacy, a seeking after the fire side, lurking in the bed, and, in short, all the characteristics of idleness, for which, in this case, I want of strength furnishes an apology. Tea drinking fills the public house, makes the frequent of it habitual, corrupts boys as soon as they are able to move from home, and does little less than the girls to whom the gossip of the tea table is no bad preparatory school for the brothel. The very least, it teaches them idleness. The everlasting dawdling about with the slops of tea tackle gives them a relish for nothing that requires strength and activity. When they come from home, they know how to do nothing that is useful. To brew, to bake, to make butter, milk, to rear poultry; to do any earthly thing of any use they are wholly unqualified."

We do not perceive how a girl's knowledge how to make tea must prevent her from learning how "to brew, to bake, to make butter &c. But we will now introduce some other antagonists of Mr. Cobbett.

An able writer in the *Encyclopedia Britannica* observes that "it must be observed by that tea is an antidote against intemperance, that he who relishes the one will seldom run to the other. Raynal says that tea has contributed more to the sobriety of this nation than the sermons, the most eloquent harangues of Christian preachers, or the best treatises of morality. We do not doubt but it may be hurtful to some particular constitutions in particular circumstances

we suspect that the nervous disorders, so often attributed to tea, are rather owing to sedentary diseases, to want of exercise, and to irregularity in food or sleep, than to tea."

Dr. Leake, an English physician of celebrity, writes that "weak tea, drunk too hot will enervate, and if too strong may prove equally injurious by affecting the head and stomach. When it is drunk in moderation, and not too warm, with a large addition of milk, I believe it will seldom prove hurtful, but on the contrary salutary. After study or fatigue it is a most refreshing and grateful repast; it quenches thirst and cheers the spirits, without heating blood; and the pleasing society in which we often partake of it is no inconsiderable addition to its value; for whatever affords rational pleasure to the mind will always contribute to bodily health."

In addition to the foregoing testimonies in favor of tea, we can, and perhaps may hereafter, cite the opinions of other eminent men, including Drs. Rush and Cooper. We have time and space at present only to say that if tea, as the Royal observance, has any effect to counteract a propensity to the inordinate use of intoxicating liquors, it is very patriotic to encourage its consumption in the United States, especially if it be true, (as we believe it is) that the tea plant may be successfully cultivated in our territories.

(TO BE CONTINUED.)

PRODIGIOUS OX!

A London paper of July 19, advertises that there is in that city the "LINCOLNSHIRE OX, fed Right Hon. Lord Yarborough," &c. The live of this animal is no less than 464 stone, which, as a stone is 3712 pounds!! This ox was a descendant from the famous Bull Comet, and the Cow Countess, of the improved Short Horns. He is the same breed with the Bull *Admiral*, belonging to the Massachusetts Agricultural Society, and of *Den-Clebs*, the former owned by Stephen Williams, of Northborough, and the latter by Col. Jaques, of Westown, Mass. The London paper says that the Lincolnshire Ox was allowed by the best judges to weigh 40 stone heavier than the famous Durham Ox, and is considered the largest, and to have the greatest proportion of meat upon the least bone, of any animal submitted to the public."

FOREIGN.

"We are apprehensive that Spanish Freedom is nobbling "on its last legs," as the phrase is. The part we can only say that we wish it may rather have nearly given it over. We expect no more of its funeral, but feel inclined to drop a tear in memory of what it might have been. Ignorance, superstition, the plagues of nations as well as of individuals, have, we fear, smothered in its cradle this noble Promise, the Desire of Nations, and the Darling of every man, who is not a brute. But there is consolation left to the friends of humanity, to wit, that Spaniards do not acquire freedom, it must be bestowed on them; they are not worthy of it. They have the power, they had the will, to secure its blessings to themselves and their posterity. We are tired of and disgusted with details of the treachery of Spanish lead-

ers, and the marches of French invaders, over a prostrate and passive population, who appear to have taken a share of the primitive curse denounced against the serpent "upon thy belly shalt thou go, and dust shalt thou eat all the days of thy life." If they should ever raise their heads as high as a black snake in pursuit of its prey, we will take further notice of them; till then—let them go.

Portugal has settled down under her resuscitated despotism as quietly as a settling-barn, and dares not even exercise the privilege of a goose to hiss at those who annoy her. A Lisbon article of July 20th, says "the monarchy is settled on the most lasting basis. The heroic queen is adored, and Gen. Amarante and his division idolized," &c. The court has no doubt become a very Pantheon of goddesses, gods, &c. Divinities will swarm, and prove as profitable to those over whom they preside as were the frogs on a certain memorable occasion to the inhabitants of Egypt. So be it—we shall not waste our paragraphs on trumpery of that description.

Bad news from Africa.—A brig lately arrived at this port brings information that the American colonists at Monrobia, in Africa, were nearly all sick of fever. Dr. Ayres, who went out to assume the government, was taken sick a few days after his arrival, and left very ill when the *Osceola* sailed. The Rev. Mr. Ashmun had partially recovered from his late illness. A fort erected by Capt. Spence had disappeared in a tornado.

DOMESTIC.

We have very little domestic intelligence this week worth relating, a circumstance we do not regret, for we have as little room as news.

The annual *Cattle Show* for Worcester County is announced in the Worcester papers for the 3th of October next. The Committee of Arrangements, appointed by the Trustees of the Agricultural Society, consists of the following gentlemen: Levi Lincoln, Theophilus Wheeler, Thomas Chamberlain, Jonathan Davis, Nathan Howe, John W. Lincoln, and Edward D. Bangs.

Longevity.—There are now living in the vicinity of Matanzas, Cuba, a couple of natives of that place, who have lived in wedlock more than one hundred years. The husband is one hundred and twenty-eight, and the wife one hundred and twenty-six years. They both enjoy good bodily health, but their mental faculties are impaired.

Mr. George B. English, of Boston, who was several years in the service of the Pacha of Egypt, has returned to Europe, with a view of taking part in the Peninsula war.

It is estimated in the Arkansas paper, that the damage sustained by the planters on the Mississippi in consequence of the late inundation, is not less than three millions of dollars.

Counterfeits.—Four Dollar Bills of New Hampshire Union Bank, are in circulation pretty well executed, except that the paper is rather darker, and the impression brighter than the genuine. A close inspection will readily detect them.

One of our late English papers mentions as a fact, that a poor woman, with an infant at her breast, employed in the grounds of Mr. Bailey, of Swanscombe, Kent, in podding peas, previous to her daily labors, suckled the child, and left it in a hedge near where she was at work. On her return some time after to look for her child, she was struck with horror at finding it dead. With the wretched mother's consent, the child was opened by a surgeon, and a snake found in its stomach. It is supposed that soon after the mother had suckled the infant, the snake, attracted by the milk remaining on the child's lips, had entered the mouth and suffocated it.—*Gazette.*

The following numbers of the first volume of the *N. E. Farmer* are wanted at this Office, for which a generous price will be given, viz.—No. 14, 5 copies—No. 33, 2 do.—No. 43, 2 do.

To Correspondents.—We have received a communication on the cultivating and curing of Hops, which we believe to be valuable, and will with pleasure give it a place in our next.

The note signed "A Subscriber," is also received, and we will give all the information in our power to afford, relative to the subjects of his inquiry, probably in our next number.

Subscribers who have not paid for the first vol. of the *Farmer*, are requested to forward us the amount due immediately; and those who wish to save 50 cents must pay for the second vol. by the 1st of October.

NOTICE.

THE subscribers who about making different arrangements in their business, feel under the necessity of calling on those indebted to them to make payment. All those indebted by Notes previous to the first of July, 1823, are respectfully requested to pay them; and all indebted by Book Account are desired to settle and close their accounts by notes or otherwise without delay.

Those whose debts have been of some time standing must consider this as all the notice necessary previous to collection in the course of law.

PROVIDENCE.

ALMIGHTY CAUSE! 'tis thy preserving care
That keeps thy works forever fresh and fair;
The sun, from thy superior radiance bright,
Eternal sheds his delegated light;
Lends to his sister orb inferior day,
And paints the silver moon's alternate ray;
Thy hand the waste of hoary time renews;
Thou shedd'st the tepid morning's balmy dews;
When raging winds the blacken'd deep deform,
Thy spirit rides commission'd in the storm;
Bids at thy will the slackning tempest cease,
And hush the angry elements to peace.
When lightning streams tremendous from the skies,
And pestilence the healing art defies,
Thy hand directs, thy word the flow suspends,
In strict accordance to omniscient ends.

See how associate round their central sun
Thy faithful rounds the circling planets run;
Still equidistant, constantly career,
Exactly tracing their appointed sphere.
Mark how the moon her flying orb pursues,
While from the sun her monthly light renews;
Breathes her wide influence o'er the world below,
And bids the tides alternate ebb and flow.
See how in course the shifting seasons rise,
And shed their potency o'er earth and skies;
Each takes its progress and its change from THEE,
All mark the presence of the Deity!

From THEE all human actions take their springs,
The rise of empires, and the fall of kings!
See the vast theatre of time display'd,
What has existed by Almighty aid,
With pomp the shining images succeed,
What leaders triumph! and what thousands bleed!
Perform their parts by Providence assign'd,
Their pride, their passions, to thy ends inclin'd:
Awhile they glitter in the face of day,
Then at thy nod the phantoms pass away;
No traces left of all the busy scene,
But that Remembrance says—the things have been!

From the Poultney (Vermont) Gazette.

Messrs. Editors—I observed in your paper an inquiry relative to the proper method of treating the disease occasioned by the poison of ground ivy. The subject is important from the great number of persons attacked annually by this infection, which usually occasions a protracted confinement and disability; and in some instances incurable ulcers and even mortification of the lower extremities.

It is a curious fact that something like one-half of the persons who are exposed to the cause of this disease are unsusceptible of its influence. I take the liberty to call the attention of your readers to the subject, chiefly with a view to state a single fact which I have on the authority of a very intelligent gentleman in this vicinity. He informs me, that for thirty years, he has known that this disease may be prevented, or rather cured, in an early stage, simply by the application of heat. His method is when he or any of his laborers have been employed in hay-making where the ivy abounds; and when in a day or two after their feet and ankles begin to exhibit marks of the disease, such as swelling, redness, heat and pain; to place them before the fire in a situation as hot as can possibly be borne without burning. This is to be done several times successively, and he assures me, that every vestige of the disease uniformly dis-

appears in a few hours. This treatment, however, is exclusively adapted to the forming stage of the disease; and to have its full effect, should be applied during the first 24 hours.—It should be stated, that although the authority for the above facts is unquestionable, yet they receive additional support from the analogy familiar to most surgeons that specific inflammations are generally cured in the incipient stages by the application of stimulants. In the second stage of poisoned legs, when small ulcers of the skin and subjacent parts begin to appear, and when the inflammation and swelling are considerable, I have seen the most decided benefit from the application of soft soap and cold water. The limb should be placed in a position as high or higher than the body, and covered with soft soap every two or three hours. Cold water should then be applied in a constant stream, or cloths dipped in cold water and changed every few minutes for 18 or 20 hours. This treatment, occasionally aided by bleeding and purging in cases where feverish symptoms make their appearance, rarely fails to remove the disease.

Poultney, Aug. 25, 1823.

☞ A correspondent of the New England Farmer, vol. ii, page 6, asserts that *lime water* is the best remedy for poison by ground ivy.

Extract from a Sermon on "Domestic Happiness," by the Rev. William Jay.

Oh! what so refreshing, so soothing, so satisfying, as the peaceful joys of home!

See the traveller—does duty call him for a season to leave his beloved circle? The image of his earthly happiness continues vividly in his remembrance: it quickens him to diligence: it makes him hail the hour which sees his purpose accomplished, and his face turned towards home: it communes with him as he journeys, and he hears the promise which causes him to hope. "Thou shalt know also that thy tabernacle shall be in peace; and thou shalt visit thy tabernacle and not sin." O the joyful reunion of a divided family—the pleasures of renewed interview and conversation after days of absence!

Behold the man of science—He drops the labor and painfulness of research—closes his volume—smooths his wrinkled brows—leaves his study—and unbending himself stoops to the capacities, yields to the wishes, and mingles with the diversions of his children.

"He will not blush that has a father's heart,
To take in childish play a childish part;
But bends his sturdy neck to play the toy
That youth takes pleasure in, to please his boy."

Take the man of trade—What reconciles him to the toil of business? What enables him to endure the fastidiousness and impertinence of customers?—What rewards him for so many hours of tedious confinement? Eye-and-bye the season of intercourse will arrive; he will behold the desire of his eyes and the children of his love for whom he resigns his ease; and on their welfare and smiles he will find his recompense.

Yonder comes the laborer—He has borne the burden and heat of the day: the descending sun has released him from his toil: and he is hastening home to enjoy repose. Half way down the lane, by the side of which stands his cottage, his children run to meet him. One he carries

and one he bears. The companion of his humble life is ready to furnish him with his plain past. See—his toil-worn countenance assumes an air of cheerfulness! his hardships are forgotten; fatigue vanishes; he eats, and is satisfied. The evening fair, he walks with uncovered head around his garden—enters again, and retires rest; and "the rest of a laboring man is sweet whether he eat little or much." Inhabitant this lowly dwelling! who can be indifferent thy comfort? Peace be to this house!

"Let not ambition mock their useful toil,
Thir homely joys and destiny obscure;
Nor grandeur hear with a disdainful smile
The short and simple annals of the poor."

"They marry and are given in marriage."

In looking over our budget of newspaper some hundreds of marriage notices come into our eye, evidencing that the fabled blind boy not less busy in our regions than he was in old antediluvian climes. What a world of pleasant thoughts the notices bring to mind—sunny days of hope, and evening courtships; love ditties, and songs, and stolen kisses, and whole train of bright attendants on the yearning days of but half enjoyed affect with the little shades of jealousy and disappointment which come to mellow the scene and ripen the harvest. Then the trembling—the cautious concealment, and careful and gradual disclosure—the scores of invitations—the smoking table, loaded with cakes and ducks and pound cake—the round for parson—and the half blushing half smiling bride.

Who thinks herself *vera well off*,
To be would an married and a'.

The printer has but poor picking out of flesh, it is true, unless, like ourselves, he has most sensitive fancy, and can feast on the ideal dainties till his stomach is satisfied. I have sometimes thought that the printer ought to be invited to the wedding supper, but it as it might involve the matter of politics, I haps it is best as it is.—*Emporium*.

A pleasant climate.—The following is the calendar of a Siberian or Lapland year:—June snow melts; July 1, snow gone; July 9, quite green; July 17, plants full growth; July 25, plants in flower; August 18, snow, coming from August 18 to June 23, following.

The lord of the village being at dinner, allowed one of its tenants to stand, while he conversed with him. "What news, my friend," said the squire—"None that I know of," replied the farmer, "except that a sow of mine has had a litter of thirteen pigs, and she only twelve teats." "What will the thirteen do?" asked the lord. "Do as I do," returned Hodge, "it will stand and look on while the others eat."

TERMS OF THE FARMER.

☞ Published every Saturday, at THREE Dollars per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

☞ No paper will be discontinued (unless at discretion of the Publisher) until arrearages are paid.

☞ Agents who procure seven subscribers, and come responsible for the payment, will be entitled to copy gratis, and in the same proportion for a larger number.

No. 7.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

ON REARING AND FATTENING SWINE.

Notwithstanding their evil propensities, filthy and insatiable voracity, swine are very profitable animals to a farmer. In every family, in which there is any thing done, should keep at least one hog, confined in a proper pen, in order to save the washing of pots, dishes, refuse &c.

much depends on the breed of swine as of domestic animal, as relates to the profit of rearing. The old fashioned, thin, long-legged, snout-nosed, gaunt-bodied hogs are now, we believe, hardly tolerated in New England, and becoming as scarce as they are ugly and unprofitable. We are but little acquainted with different breeds of their successors, and shall therefore assume the responsibility of recommending any particular race. O. Fiske, of Worcester, an able, enlightened, and judicious cultivator, says, "my hogs are of the old breed, so called in England; and experience has proved, to my satisfaction, that this is far the best that has been introduced into our country. They are quiet in their nature, easy and with little expense or trouble, they had some weight, at twelve months old, 310 pounds, and a considerable number of them months old, 400 pounds."*

"The marks of a good hog are a moderate size, in proportion to the size of the body; a short neck; the cheek plump and full; neck short and short; quarters full; carcass thick and full; hair fine and thin; with a symmetry suited to the breed to which it belongs. Above all it is essential that it be of a kindly disposition to fatten early."†

A sow should be selected with great care, and straight-backed; wide hips; a great number of teats; short legs, and fine bone. It is essential that the sow will produce the stronger and earlier litter, if not allowed to breed till a year and the boar should not be younger than three years when put to sows. Sows may be allowed to breed till they are six years old, and till five; and both be made good porkers in their period, by methods which do not require description. One male, according to the *late Graciere*, should not be permitted to have access to more than ten females in a year. He will, usually, have pigs twice a year, and may be put to the males at such times as will produce one litter in April, and another early in June.

Those sows are accounted the best breed—says the Farmers' Assistant, "which have ten or twelve pups. They should be kept clean and well littered; but should not have too much litter at the time of pigging, lest they overeat their pigs in it. At the end of a week or ten days, they should be let out of their sties into the yard, for three or four hours each day. In several sows are farrowing about the

same time, they must be kept in separate apartments in the sty lest they devour the pigs of each other. Young sows will sometimes eat their own off-spring, which may be prevented by washing the backs of the pigs in an infusion of aloes; and, for this purpose, the sows must be watched. It is said that supplying them with plenty of water, at this time, will prevent any mischief taking place of this kind."

Mr. Featherstonhaugh says, "Farmers differ much in their plans of raising holding stock for pork; some permitting their shoats to run at large eighteen months, till they are penned up to fatten; this is the most troublesome and least profitable way; others give them a range in clover pastures, and begin to fatten them earlier. I apprehend there is a much more profitable way, and attended with less trouble for those who have the right breed. According to the quantity of pork wanted should be the number of breeding sows kept over, and there should be no other hogs on the farm [that is kept over winter] but the breeding sows. These, when they pig the latter end of March, should be fed in the most attentive manner, with swill and shorts. The pigs from a full grown sow, will generally be twelve in number; these should be thinned down to eight, and as soon as they begin to feed freely out of the trough should be weaned, and afterwards fed regularly with green turneps, clover, boiled potatoes, ground peas, unmerchantable corn, or any other nourishing food; turning them out every day into a small yard, where there is a shallow pond for them to lie in. A remarkable breed of pigs, which had been treated pretty much in this manner, were exhibited at Duanesburgh Fair; when eight months old, one of them was slaughtered, and weighed exactly three hundred and eleven pounds; they all attracted universal attention, and I never saw such animals before. This method, as it is attended with little trouble, and leaves so small a quantity of stock on hand to winter over, appears to me to be more economical in every point of view, than any other which is practised."* In the county of Rensselaer, N. Y. some farmers assert that "March pigs, killed about Christmas, are the most profitable for pork." Others say, "Pigs ought never to come until June; for the cost of earlier pigs exceeds the profit." And further we learn that "the methods proposed for fattening hogs by the different farmers in that county are very various. Gen. H. Moffit, H. Platt, Esq. Col. Worthington, Messrs. J. Phillips, A. Bush, and some others, recommend keeping hogs in pastures with some slops from the dairy, &c. till near the last of August—some say a little later. All agree that near this time they manifest a disinclination for grass. Small patches of peas, or even of corn, will then be convenient to turn them into for a few weeks. About the first of September begin with boiled potatoes and pumpkins, mashed together with a little Indian meal, ground oats and peas, or other grain, stirred into the mixture after it cools.—

From two to four weeks before killing time, the food should be dry Indian corn, and clean cold water. Mr. Vaughan fattens his hogs in a large yard or field, with a shelter in it to which they may retire to sleep. But Elder Turner says—hogs should never know what liberty is; but should be kept close all their lives, and as inactive as possible. That with this method double the quantity of pork can be produced with the same expense of feed."‡

The practice in Scotland is to rear swine chiefly on raw potatoes, and to fatten them on these roots boiled or prepared by steam, with a mixture of oats, barley, or bean and pease meal. Their troughs should be often replenished with a small quantity of food at a time, and kept always clean and seasoned occasionally with salt. The Farmers' Magazine says, "The outside leaves of cabbages suited and let stand a month, and then mixed with butter-milk, will fatten a hog in three weeks." Mr. Marshall says (*Midland Counties v. p. 453*) "young pigs require warm meat to make them grow. Corn and cold water will make them healthy; but warm beverage is considered as requisite to a quick growth." The same writer mentions another practice, which perhaps it may be thought proper to imitate in this country, because it saves labor and care. Some English farmers, he says, keep two or three little store pigs in the fattening sty. While the fattening hogs are taking their repast, the little ones wait behind them; and as soon as their betters are served, lie out the troughs.

Beside the advantage of having by this expedient no waste, nor foul troughs, there is another. The large pigs rise alertly to their food, lest the small ones should forestall them; and fill themselves the fuller, knowing that they have it not again to go to.

"The disadvantage of this practice is, I understand, the large ones are apt to lord it too much over the little ones; especially in a confined sty. If, however, they had a separate apartment assigned them, with an entrance too small for the fattening swine to follow them, this disadvantage would be in a great measure remedied."

If one wishes to fatten hogs, and either from indolence or too much occupation does not expect to give them a constant and regular attention, perhaps he may adopt to advantage the following mode pointed out by an English writer. Mr. John Adams, of Cherrington, near Newport, Shropshire, has fattened eight pigs in the following cheap and easy manner:—he places two troughs in the sty, one he fills with raw potatoes, the other with peas, and gives no water; when the pigs are dry they eat the potatoes. The eight pigs were fattened so as to weigh from 16 to 20 score each, and ate no more than 50 bushels of peas, and about 200 bushels of potatoes. No doubt dry Indian corn and potatoes might be fed out in this way with as good an effect as peas and potatoes.

* Memoirs of the New York Board of Agriculture, vol. ii, pp. 39, 40.

† Report of Agriculture in Scotland.

New England Farmer, vol. i, p. 107.
Farmers' Assistant.

* Memoirs of the New York Board of Agriculture, vol. i, p. 222.

Robbing and currying the hides of fattening hogs, is of great advantage to them. It is not only very grateful to them, but conducive to their health. It will be well, likewise, in every sty to place a strong post for the animals to rub against. During the time of their fattening they should have plenty of litter, which will be a double advantage, providing for the comfort of the animal, and increasing the quantity of manure.

Boiled or steamed clover hay will, it is said, keep store hogs in the winter, but the addition of boiled or steamed potatoes or carrots will much increase the value of the wash. Mr. Young directs to soil or feed swine in a yard on clover, cut up with a scythe, in preference to pasturing them in the field. But Judge Peters, of Pennsylvania, says, "in summer my hogs chiefly run on clover. Swine feeding on clover in the fields will thrive wonderfully; when those (confined or not) fed on cut clover will fall away." In Indian harvest, the unripe ears of corn should be picked out and given to the hogs as fast as they can eat them. Soft corn (as it is called) will do them much more good in a green than in a dried state, and it is very difficult to dry it without its turning mouldy.

There is a great advantage in boiling, steaming or baking almost all sorts of food given to swine. The last American edition of the Domestic Encyclopedia, informs that Mr. Timothy Kirk, of Yorktown, Penn. fed one pig with boiled potatoes and Indian corn, and another with the same articles unboiled. The two animals were weighed every week, and the difference between them was 6 to 9. The experiment was continued several weeks, and the animals alternately fed upon boiled and unboiled food, with a uniformity of result, which sufficiently showed the very great profit arising from boiled food.* Steaming will answer as good a purpose as boiling, and with a proper apparatus, may be more easily and cheaply effected.* Potatoes, meal, and a little linseed boiled together, make a rich and excellent wash. Boiled linseed, it is said, has a tendency to make pork soft and oily, and should therefore be but little if at all used towards the close of the time in which hogs are fattening. Grains of distilleries, and the refuse of starch-factories are excellent for fattening swine. Sweet apples are very good food for them, and a change of diet pretty often promotes their health and quickens the process of fattening. Their meals should frequently be seasoned with a little salt. The Complete Farmer says that "moist sedgy grounds are good for swine, the roots which grow in such soils they will eat; likewise brakes, ground nuts, acorns, chestnuts," &c. Dr. Anderson said that the hogs that are fed upon the acorns that they gather in the woods of Germany and Poland are reckoned to yield the finest bacon of any in Europe; and it is to this that most people ascribe the superior excellence of Westphalia hams. It might be well to try acorns steamed or boiled, in order to correct their crudeness and bitterness; and it has been recommended to moisten them, and keep them on hand till they begin to sprout, when they will be more sweet and nutritious than in their original state. The Complete Farmer asserts that "when hogs are fattened entirely on acorns, chestnuts, and other

productions of the forest, the flesh will eat much better and sweeter than if fattened in a sty. Some indeed say their fat will not be so solid, nor so profitable, and therefore they commonly shut them up a week or ten days, and feed them with dry peas; but this is a mistake, experience having shown that hogs, fattened with acorns only, have their fat as solid as those fattened with peas." If this be correct, the value of acorns as food for swine is not generally known in those parts of the United States with which we have been acquainted. We have seen places in the neighborhood of farmers' dwellings, where bushels might be had for stooping, but were as much neglected as if they had been pebble stones. The acorns recommended are, we believe, those of the white oak; and whether the acorns of the numerous other kinds of oak are of any value as food for swine we cannot say. It might be well to try them not only raw, but boiled or steamed, and likewise ground into meal and given with, as well as without other mixtures. We suspect that acorns alone would prove astringent, and if so, they might be qualified with a trough full of raw potatoes.

Carrots, according to Mr. Young, are better than potatoes, and some other writers assure us that parsnips are better than either for feeding hogs. An English writer says "they fatten all their pork in the island of Jersey with parsnips. They are much more saccharine than carrots, and it is well known that nothing fattens a hog faster, or makes finer pork than the sugar cane;" and we are told that parsnips suffered to remain in the ground where they grew through the winter, and drawn in the spring and boiled tops and bottoms made most excellent food for swine, when other food was scarce.

Acid or fermented food for swine has been highly recommended. Mr. Arthur Young, whose authority amongst husbandmen is almost equal to that of the Pope with Roman Catholics, says "that the most profitable method of converting corn of any kind into food for hogs is to grind it into meal, and mix this with water in cisterns in the proportion of five bushels of meal to one hundred gallons of water, stirring it well several times a day for three weeks in cold weather, or a fortnight in a warmer season, by which it will have fermented well and become acid, till which it is not ready to give. The mixture should always be stirred immediately before feeding, and two or three cisterns should be kept fermenting in succession, that no necessity may occur of giving it not duly prepared." Judge Peters, of Penn. whose authority is, in our opinion, not inferior to that of any man who ever wrote on agricultural topics, says, in substance, that "sour food is most grateful and alimentary to swine. One gallon of sour wash goes farther than two of sweet." But

An English work entitled "Farmers' Calendar," (author's name not given) declares that "much has been said, and little understood, about purposely souring food for hogs. It is not that acidity can possibly tend to pinguification [making fat] but it is found that pigs will readily fatten upon acid, or rather acedent food, a sweetish taste and glutinous quality succeeding fermentation; and that they will do so still more readily upon such as have never reached the acid state I know, and have seen in hundreds of instances. Is a proof wanted? How much more rea-

dily do the country hogs feed upon sweet than unfermented food than those of the starch-ho upon the fermented and sub-acid wash, however rich? I say sub-acid, for did not starch-making run off a great part of that which is really acid, they would kill instead of fatten their hogs." In order to reconcile these writers it will be necessary to advert to the different stages of ordinary fermentation, and the products of each stage. The first stage of fermentation produces sugar, and is called the saccharine fermentation. The second stage develops alcohol, or spirit of wine, and is called the vinous fermentation. The third do. produces vinegar, and is called the acid fermentation; and the fourth and last stage converts the matter fermenting into a substance which is not only offensive but poisonous, and is called the putrid fermentation. Thus if you soak wheat or other farinaceous substance in water of a proper temperature will first become sweet, and begin to sprout and vegetate; it will next afford spirit or alcohol, continue the process the wash turns sour, first slightly, and then more strongly acid; at last the whole becomes putrid. It probably contains most nourishment when it is sweet, but is valuable till very sour, when it is worthless or nothing; and when the putrid fermentation has commenced it is worse than nothing as food for any animal. The farmer then should give his wash to his pigs while it is yet sweet or but beginning to turn sour.

The following will corroborate what has before been published in the pamphlet entitled "Remarks on the Dangers and Duties of Sepulture," (viewed in our paper, vol. i. p. 394.) relative to the very virulent nature of the poison which is produced by dead bodies in some stages of putrefaction, and serve as a caution against unnecessarily tampering with substances which are as injurious to our health as they are offensive to our senses.

FOR THE NEW ENGLAND FARMER.

Saint Pierre, in his *Studies of Nature*, vol. p. 211, first American Edition, in combats some of the infidel philosophers on the subject of equivocal generation, says: "It is not on certain that corruption produces no one living body, but is fatal to all, especially to the which have blood, and chiefly to man."

"No air is unwholesome, but where there is corruption, which, so far from conferring life, generates tubercles, inflames the eyes, dissolves the blood, and produces an infinite number of diseases in most animals, which respire its emanations."

"Of all corruptions, that of the human flesh is most noxious. Of this a very singular instance is related by Garcilaso de la Vega, in his history of the civil wars of the Spaniards in the India Vol. I, part 2, Chap. 43. He observes, first that the Indians of the Islands of Barlovento poison their arrows, by plunging the points of them into dead bodies; and then adds, 'I shall relate what I myself saw happen in the case of one of the quarters of the dead body of Carnajal, which was exposed on the great road to Collosigu, to the south of Cusco. We set out walking one Tuesday, ten or twelve school-boys of us, all mongrels, that is, the progeny of Spaniards by Indian women, the oldest not above twelve years of age. Having observed as we went along in the open country, one of

quarters of Carvajal's body, we took a fancy to and look at it, and having come up, we found it was one of his thighs, the fat of which had dropped to the ground. The flesh was black, and entirely corrupted. While we were examining this mournful spectacle, a foreign boy chanced to say, I could wager no one dares to touch it; another replied, he would. At last the stoutest of all, whose name Bartholomew Monedero, imagining he was going to perform an act of courage, plunged his thumb of his right hand into this putrid mass, which it easily penetrated. This boldness astonished every one to such a degree, that we all ran away from him, for fear of infection, calling out, Oh! abominable! Carvajal make you pay dear for this rashness. He, however, instantly to the brook, which ran close by the spot, washed his hand several times, rubbing it over with clay, and so returned home. Next day he returned to school, where he shewed us his thumb, which was swollen prodigiously; but towards evening the hand had become inflamed up to the elbow; and next day, which was Thursday, the hand swelled up to the elbow, so that he was reduced to the necessity of disclosing the wound to his father. Professional men were immediately called in, who had the arm tightly bandaged above the swelling, and applied every remedy which art and experience could suggest as a counter-poison. After all, notwithstanding, it nearly cost the patient his life; and he died covered not without suffering intolerable pain after having been for four months so ended as to be incapable of holding the pen." This anecdote it may be concluded how enormous the putrid emanations from our churches must be to the inhabitants of cities. Parishes, churches, in which so many corpses are interred, become impregnated with an air so corrupted, especially in spring, when the ground begins to grow warm, that I consider this as one of the chief sources of the small pox, and of the putrid fevers which are prevalent at that season. An unsavory smell then issues from it, which makes the stomach rise. I have felt this insufferable degree in some of the principal churches of Paris. This smell is extremely different from that produced by a crowd of living people, for we are affected with no such infection in the churches of convents, where the dead only are interred."

FOR THE NEW ENGLAND FARMER.

EDITOR—I have been always disgusted with the huge heaps of pomage (or pomace, as it is commonly called) which are found adjacent to the cider house, and as they contain much vegetable matter mixed with the malic and acetic acids, I thought that if those acids could be neutralized at a small expense, a new article might be added to our manures, and a disgusting object removed out of sight. Accordingly spread on the pomage a quantity of leached ashes, to the depth of one quarter the bulk; this was heaped and lay all summer to give the alkali a chance to work on the acid. In the fall I hauled out on to my grass land and in April spread it very thick, say 14 or 15 ox cart loads to the acre. The effect exceeded my most sanguine expectations, and the grass was doubled. It has been suggested to me that the effect was

probably produced by the leached ashes, I took as great, or greater quantity, of leached ashes and spread on the ground adjoining. The effect was trivial in comparison to the other, but some allowance must be made for its being applied a month later. This is barely one experiment—it might not succeed on a different soil or under different circumstances. The land on which I spread it had been exhausted by frequent mowing. *Unleached* ashes would undoubtedly answer better than leached, and perhaps line the best of all. The experiment is easily made. I wish others would try it and publish the result. Yours, &c. N. AGRICOLA.

Minot, Maine, Sept. 1823.

An Example worthy of Imitation.

A Committee has been appointed by the S. Carolina Agricultural Society, to consider what beneficial effects would result to the agricultural interests of the State, by importing Foreign Seeds, Plants, and Implements of Husbandry. This Committee have submitted to the Society by which they were chosen, several resolutions from which we have made the following extracts:

"1. That the sum of two hundred dollars be annually appropriated to the purchase and importation of foreign seeds and plants.

"2. That a Committee to consist of three members, be appointed; to be denominated the *Importing Committee*; whose business it shall be to import such seeds and plants as may be designated by the Society, or, for want of such designation, as they may deem calculated to improve the Agricultural interests of the State; and that, for this purpose, they shall correspond with the Consuls of the United States, and such other persons as they may think proper, in countries not differing in a considerable degree in climate and situation from our own, where valuable articles are the product of the soil. And, as your Committee have observed, with pleasure and with pride, that the officers of our Navy, not confining their patriotic exertions, to elevating the glory of our country and protecting its commerce and its coasts, have, with intelligent zeal added to its Agricultural prosperity, by the introduction of various valuable animals and plants; it is recommended, that the importing Committee, should, through the proper channel, communicate to the Naval Department, the views of the Society; respectfully soliciting their aid in carrying them into effect. It is likewise recommended that the Committee shall select from the publications containing them, or obtain elsewhere, the best mode of packing and preserving the Seed, a copy whereof shall accompany the orders for their importation; directing, in general, that they shall be forwarded so as to arrive in this country, and be sown, within a twelvemonth from the time when they were gathered; but where this cannot be effected, advising the most efficient mode to be adopted for their preservation, particularly in guarding them against the influence of the atmosphere.

"It is also important, that, with the Seeds or Plants which they may obtain, the Committee should endeavor to procure accounts of the mode of culture and soil best adapted to them, and information of the time they occupy in com-

ing to maturity. And, as we cannot rely on an exemption of more than eight months from frost, it is deemed advisable that no annuals liable to be injured thereby, should be imported, provided it requires more than that period to arrive at maturity.

"3. That the seed, when imported, shall be distributed *gratis* to the members of the Society, and portions of it presented to our sister Societies in the State, and to any other individual to whose skill and intelligence the Society may wish to intrust them; requesting, in all cases, that the result of their trial shall be communicated to the Society."

The Committee consists of the following gentlemen: Thomas Pinckney, John D. Legarde, Elias Horry, Nathaniel Heyward, and Charles E. Rowand.

From the American Farmer.

Domestic Economy.—Every housewife ought to be informed, that a very useful and economical utensil has been lately introduced here from Philadelphia, which may be called a *conserving furnace*; by means of which great saving is attained in the cost of fuel, and the person using it, instead of stooping frequently before a large wood fire, places it on a table in her kitchen or breakfast room, and with a cent's worth of charcoal prepares a large dish of fruit. These furnaces are of different sizes and of the shape of the common copper skillet. To have an idea of its construction, the fair reader may imagine a stone milk pan, were with we suppose them to be familiar—with sides nearly straight, and with two bottoms. so to say, with an hollow space between them, of about two inches—the upper bottom on which the charcoal is placed, is perforated with several holes, the size of a piston; or rather the holes are left in the clay, when the furnace is baked to the consistence of rough stone. There is then a little aperture, or door, left through the outside of the furnace, to admit the air between the two bottoms, by means of which the charcoal is made to burn; should the fire become too brisk, and the stewing of the fruit proceed too rapidly, this aperture below is closed, which immediately checks it. We are told by ladies who have used them, that the idea of this furnace must have been conceived, like the Frenchman's new fashioned shoe, in "a moment of enthusiasm," and that it is in short regarded, in their department, as one of the grandest inventions of modern days. It is easy to see that it saves the person from distressing exposure to heat, and is far more cleanly and economical, than the old way of conserving fruits.

The Durham Chronicle states the complete success of an ingenious plan of constructing boilers for melting fat, kitchen stuff, &c. so as wholly to remove that offensive effluvia so much complained of by those in the neighborhood of tallow-chandlers' melting-houses. The tube or chimney is constructed in such a way as to make the foul vapour of the boiler pass through the fire, where it is wholly consumed. The fire, which is equally applied to the boiler all round the exterior, is supplied with atmospheric air from above, the ashpit being completely closed. There is also a considerable saving of fuel and of time in the process.

FOR THE NEW ENGLAND FARMER.

Thomas G. Fessenden, Esq.

SIR—The cultivation of Hops is becoming an important branch of Agriculture with our farmers, both as an article for exportation and domestic consumption. The quantity now raised in this country, annually, does not vary much from a million of pounds. Great improvements have been made, within a few years, in the cultivation and management of this article; and with such success, that we have had several lots which would compare (without prejudice to their reputation) with the best English hops. In consequence of which, our Hops are gaining a fair reputation abroad; and our home consumption is rapidly increasing;—a prospect highly gratifying to every friend to society, to see the wholesome liquor made from this article introduced, and supplying the place of ancient spirits.

If, Sir, you deem the following observations on the culture and management of Hops, worthy a place in your paper, you are at liberty to publish them.

Yours respectfully, &c.

WILLIAM BLANCHARD, JR.

Wilmington, August 26, 1823.

The Hop is a native plant. It is found growing spontaneously on the banks and intervals of many of our large rivers. There are several distinct species, all bearing a near affinity to each other; (I have noticed five.) At present they are cultivated together, promiscuously; no preference having been given to any particular one of them by the brewer. But I am of the opinion that there is an essential difference in their qualities—that one may be the best for pale ale; another for strong beer; and a third for porter; and I presume, ere long, particular attention will be paid to ascertain their different qualities.

The soil best calculated for the production of Hops, I consider to be a sandy loam, rather low and moist. I am led to this conclusion, partly from my own observation, and further, (considering Nature an infallible instructor,) from finding the lands which produce them naturally (intervals and the banks of large rivers) to be of this kind. Yet, I must observe, I have seen very fine crops raised on very different soils.

I should recommend the following mode of preparing the land and managing the crop. In the fall (October) plough the land deep—nine or ten inches. In the spring following, pass a heavy, sharp iron toothed harrow over the land in the same direction it was ploughed; after which, spread your manure evenly over the same, sixteen cords per acre, and more if the land be much reduced; then cross-plough the land nearly the same depth, and furrow it as for planting corn—the furrows to be at least four feet apart.

It is customary to plant corn or potatoes with the Hops, (I should prefer potatoes.) Plant every other hill in every other row with hops, thus placing the hop hills at least eight feet apart. Put four cuttings, from the running roots, about eight inches in length, into each hill, and cover them the common depth of potatoes.

Many yards have been much injured by being planted too closely. It is of great importance to have the hills so far distant from each other as to admit a free current of air to pass through the yard.

All the attention requisite the first season, after the Hops are planted, is to keep them clean from weeds, which is easily done when hoeing the crop planted amongst them. In the fall, (October) to prevent their being injured by the hard frosts of winter, carry on, and lay out of your cart, one shovel full of compost manure on the top of each hill;—manure from the hog-stye I should prefer.

In each following spring, before the hops are opened, as it is termed, spread evenly over the yard about eight cords of manure per acre,—(coarse, strawy manure, I should prefer, as it will have a tendency to keep the land loose;) and plough the field both ways at the first hoeing. They require but three hoeings in a season, unless necessary to subdue the weeds; the last of which should be performed when the hops are in full blossom, (about the beginning of August.)

After the first crop, it is necessary to open the hops, every spring, by the middle of May; which is performed by making four furrows between the rows, turning the furrows from the hills, and running the plough as near to the same as possible without injuring the main roots. Then the earth is removed from the roots with a hoe—all the running roots cut in, with a sharp knife, within two inches of the main roots—the tops of the main roots must also be cut in—and then the hills covered with earth about two inches deep.

The next thing, necessary to be done, is to set the poles. This should be done as soon as the hop-vines begin to make their appearance. By so doing, much time and labor will be saved in tying up the vines to the poles, as many of the vines will naturally take to the poles.—There should not be to exceed two vines to one pole, nor to exceed two poles to one hill, nor any pole to exceed sixteen feet in height. Many yards have been very much injured by letting a greater number of vines grow on one pole; and almost destroyed by over-poling.

Very much depends on paying due attention, in the spring, to select the most thrifty vines, and training them to the poles, which is done by fastening them to the poles with a piece of yarn, slightly twisted together with the thumb and finger.

It will be necessary to inspect your hop yard frequently, until the hops begin to blossom, and "to tie up the vines," as it is termed, as they are subject to be blown off the poles by every high wind.

As soon as the hops are ripe, which is about the beginning of September, they must be immediately gathered, or the crop is lost. The quality of the hops depends considerably on their being picked clean from leaves and stems. The labor of picking or gathering the hops, may be well performed by women and children, having one man to a bin to handle the poles, and to inspect the pickers. The bin is a wooden box, about nine feet long, three feet wide, and two and a half feet high, made of thin pine boards, that it may be easily moved over the yard, across which the poles are laid, and into which the hops are picked by hand. Care should be taken, when gathering the hops, to cut the vines two feet from the ground, that the roots may not be injured by bleeding.

The most important part in the management of hops, is the curing or drying of them. Here

I would note, that hops always grow first sort and that all second sort and refuse hops, are made so by unfortunate or unskilful management.

Much depends on having a well constructed kiln. For the convenience of putting the hops on the kiln, the side of an hill is generally chosen for its situation. Care should be taken that it be a dry situation. The kiln should be about the same bigness at the bottom as at the top; the side walls laid up perpendicular and filled in solid with stone to give it a tumb form. Twelve feet square at the top, two feet square at the bottom, and at least eight feet deep, is deemed a convenient size. On the top of the walls sills are laid, having joists let in them in like manner as for laying a door—which joists, about $1\frac{1}{2}$ inches wide, are nailed leaving open spaces between them $\frac{3}{4}$ of an inch over which a thin linen cloth is spread, a nailed at the edges to the sills. A board about 12 inches wide is set up on each side of a kiln, on the inner edge of the sill, to form a bin to receive the hops. The larger the stone made use of in the construction of the kiln, the better; as it will give a more steady and dens heat. The inside of the kiln should be well plastered with mortar, to make it complete air tight. Charcoal (that made from yellow birch or maple I should prefer,) is the only fuel proper to be used in drying hops. The kiln should be well heated before any hops are put on, and carefully attended to keep a steady a regular heat.

Fifty pounds of hops, when dried, is the largest quantity that should be dried, at one time on a kiln of this size; and unless absolute necessary to put on that quantity, a less would dry better. The green hops should be spread as evenly and as light as possible over the kiln. The fire at first should be moderate, but it may be increased as the hops dry and the steam evaporated.

Hops should not remain long in the bin bag after they are picked, as they will very soon heat and become insipid. The hops should not be stirred on the kiln until they are completely and fully dried. Then they should be removed from the kiln into a dry room and laid in a heap, and there remain, unmoved and undisturbed, until bagged, which is done with a screw, having a box made of plank the size of the bag is wished, into which the cloth is laid, and the hops screwed into the box, which is so constructed that the sides may be removed, and the bag sewed together while in the press.

The hops, after laying a few days, will gather a partial moisture, called a sweat. This sweat will probably begin to subside in about eight days, at which time, and before the sweat is off, they ought to be bagged in clear dry weather. As the exact time when the hops will begin to sweat, and when the sweat will begin to subside or dry off, (the proper time to bag them) will vary with the state of the atmosphere, it will be necessary to examine the hops from day to day, which is easily done by taking some of them from the centre of the heap with your hand. If on examination you find the hops to be very damp, and their color altering,—which will be the case if they were not completely dried on the kiln, and not otherwise—your next overhale them and dry them in the air.

The most convenient size for a bag of hops handle and transport, is about five feet in length, and to contain about 250 pounds. The st bagging is coarse strong tow cloth of our domestic manufacturing; next to that, Russia tow bagging. The East India sugar, and gurney bags, so called, ought never to be used. The sugar bags are of an unreasonable weight, and both they and the gurney bags are of no use to the brewer; whereas the other bags are worth prime cost.

It is now common for those who have entered considerably into the cultivation of hops, to add houses over their kilns, which, in wet weather, are very convenient; otherwise, a kiln in the open air, would, in my opinion, be preferable. It is necessary to have these buildings well ventilated with doors and windows; and to have them kept open night and day, except in wet weather, and then shut those only which are necessary to keep out the rain. If an ventilator was put in the roof of the building, directly over the centre of the kiln, about six feet square, built like those in breweries and distilleries, I am of the opinion they would be of very advantageous. I have seen many kilns of hops much injured, both in color and flavor, by being dried in close buildings.

Where the houses over the kilns are built large, for the purpose of storing the hops as they are dried,—which is a great saving of labor,—a close partition should be made between the kilns and the room in which the hops are stored, to prevent the damp steam from the kilns coming to them, as it will color them and impair their flavor and quality very much.

I expect that many of our farmers will object to the mode of manuring hops which I have recommended, their common practice being to manure in the hills when they plant the hops, and afterwards to apply the manure to the hills at the first and second hoeings. In the hop-roots are very liable to be injured by worms, and to decay. My opinion is, that manure in the hill has a tendency to produce the worms, and its fermentation at their roots to cause their decay; and that the crop is not more, if as abundant, as when manured in the manner I have recommended. And further, that a hop yard manured in this manner, will continue in a healthy state for many years.

I also expect the quantity of manure I have recommended, will be objected to by many, on the common received opinion that hops should have little or no manure. I find it a general complaint amongst the farmers where hops have been cultivated many years, that the quantity raised per acre does not exceed the half raised by their ancestors, on the same soil; inferring that the "hops are running out," as is termed, and cannot now be cultivated to advantage. Hops, I believe, in common with sorts of grain and vegetables, flourish best on the finest crops, when cultivated on lands which require little or no manure—such were the lands which their ancestors cultivated. The same complaint I presume would be made against all sorts of grain and vegetables, if raised with little or no manure, and that have long been cultivated.

From my own observation, I am confident that no crop can be more improved and increased in high cultivation than hops.

From the Hallowell Gazette.

WINTER WHEAT.

Messes. Peabodys—Having been for several years successfully engaged in the cultivation of winter wheat, I think it may be interesting to some of your readers to know the result of my experiments.

I was led to its cultivation, by observing it to be one of the staple commodities of the middle States, where the winter is unequal and variable, and where the ground is occasionally frozen to as great a depth, as in Maine, without any covering of snow to protect it; and where severe cold and sudden thaws sometimes alternate through the winter. I was also informed by a gentleman residing on the St. Lawrence, in the State of New York, that winter wheat was successfully cultivated in his neighborhood, in a climate similar to that of Maine, although a prejudice had existed there, as it does here, that it would not bear the severity of our winters.

My first experiment was made five years since, with seed brought from New Orleans. Having been informed in the middle States that wheat sown late was not so liable to be injured by the Hessian Fly, as when sown early, I did not sow mine till October. It was sown on light soil, and in the spring looked well. It was however struck with rust before it was ripe; and the crop was very much injured. As the winter had not injured my wheat, I was not discouraged, but have every year since sown wheat at different periods, between the last of August and tenth of October. All that I have sown on light soil, has looked well in the spring; but what was sown late, that is, after the middle of September, has been invariably struck with rust before it was ripe; while what was sown early has as invariably given a good crop. Most of my experiments have been made on green-sward. After haying, I have selected a piece of ground, which required ploughing, and generally of a light loam. I have ploughed it once, and harrowed it twice or thrice, putting on between the harrowings from 15 to 20 loads of manure to the acre, and sowing the seed before the last harrowing. I have always fed it in the autumn, believing that it would be less likely during the winter to mould or die, if eaten close, than if left long on the ground. I have found that the lighter the soil, the less liable was the wheat to be destroyed by the winter; but this is of less importance than at first might be supposed; for each remaining root, sending up from 10 to 20 heads in the spring, will supply the places of a great many killed in the winter. One piece that I raised this season, on rather heavier soil than I had been accustomed to cultivate with wheat, appeared in May to be two thirds dead, but when I reaped it in July the ground was nearly covered with grain; and it has yielded probably 20 bushels to the acre. I have never accurately measured my ground and crop but once: which was last year, when I raised 40 bushels of excellent wheat upon one acre 125 rods of land, being 21 bushels 29 quarts to the acre. This wheat weighed last autumn from 65 to 66 lbs. the bushel; one bushel last week weighed 63 lbs. having probably become lighter by drying. A bushel of the same wheat gave 50 lbs. 10 ounces of flour, the toll having previously been taken out.

The cultivation of winter wheat is preferable

to that of summer wheat on a great variety of accounts. It is sown, and the ground prepared, at a season of much greater leisure. One of the greatest disadvantages of our northern climate is the extreme shortness of our spring, so that it is difficult for our farmers to complete the work, which is absolutely necessary to be done, after the frost is out of the ground, and before the season of planting is over. If therefore any work, as the sowing of wheat, can be advantageously postponed till the autumn, it is of great importance. The winter wheat is less liable to injury from insects than the summer; mine has never suffered from them. It affords good fall feed, and the larger quantity of roots and stubble to be ploughed in make the land in a better state for the next crop. The grain is heavier, and the same number of pounds will yield a larger quantity of flour, and of a much superior quality. For these reasons, it cannot be too strongly urged upon the attention of our farmers. From my experience I should recommend that winter wheat should not be sown later than the middle of September, that the soil, on which it is sowed, should be a light loam, and that about five pecks of seed be sown to the acre. I have also found the use of plaster on wheat advantageous, as also rolling the wheat after it was well up. Winter wheat might probably do better after peas and beans than on green-sward. I intend trying it after both and also after a summer fallow, but have not hitherto done it.

R. H. GARDINER.

OAKLANDS, Gardiner, July 30, 1823.

From the Glasgow Journal, (Scotland.)

MANGEL WURZEL.

Mr. John Hall, of Little Marshall, Ide, near Exeter, recommends the cultivation of Mangel Wurzel. The land is dressed, drilled, and manured in the same way as turnips are cultivated in Scotland. The seed is covered not more than an inch deep; when up, and having six leaves, let the plants be hoed out to one foot distance in the rows, which, (the rows,) if two feet apart, will give upwards of 20,000 plants an acre; and should these average 10 lbs. each, (I had many last season upwards of 18 lbs. although an unfavorable time prevailed,) the produce would be between 80 and 100 tons of food.

Keep the intervals horse-hoed as often as convenient, and as long as the luxuriant growth of the leaves will permit. The seed-time for this plant is best between the 20th of April, and the 1st of May, by which last named period those who are desirous of a superior crop will do well to have their sowing finished.

The same care that is bestowed on potatoes for their goodly preservation is requisite for well keeping mangel wurzel; and it is of particular consequence that the roots be housed in dry weather, and before frost sets in, as, if housed wet, they are apt to get woolly and bad tasted, (not, therefore, so suitable for milch kine for whom they are, when good, peculiarly desirable;) and, if frosted, they become slimy and rotten, or what is provincially termed here, "they slope away." When taken care of, by caving or housing in a dry situation, they will remain good till May or June. If these roots are given carelessly to cattle when first taken up, or, to speak generally, any time before Christmas, they, containing as they then do so much moisture, are apt to blast and scour them.

and I have seen intoxication produced by them, given fresh-gathered, and in too great quantity; and had not bleeding been had recourse to, death would have ensued. All that is necessary to be observed in the early season, is, that the supply of roots be moderate at a time, and hay, straw, or chaff, given between the servings with mangel wurzel; as the season advances, the quantity of roots may be increased, and the dry food diminished. Milk and butter from mangel wurzel are peculiarly sweet and fine; and beef, produced from feeding with this root, is excessively juicy and rich flavored.

The root will not require such excessive deep land as many have imagined, its chief growth being out of the ground; and though much benefited by frequent hoeing, it is by no means right to earth it up, as by that plan the growth is retarded till fresh fibrous roots are thrown out in search of nourishment near the new made surface of the surrounding earth.

Nor let the grower of mangel wurzel shrink from giving his field an ample supply of good rich manure, as his well fattened land will return him five-fold profit if he gives it with an unsparing hand.

And now, though last, not least, for the cultivator's consideration, mangel wurzel is not subject to the depredations of the turnip beetle.—Neither will that farmer be troubled with smut in his corn who steeps his seed wheat in a solution of sulphate of copper.

On setting Cutting Instruments.—The thanks of the Society for the Encouragement of Arts, Manufactures and Commerce, were voted to George Peverley, Esq. of Queen-Square, London, for a communication on the use of soap instead of oil in setting cutting instruments on a bone. It sets quicker, gives a good edge, removes notches with great facility, and is a much more cleanly material than oil. The operation is performed as follows:

Having first cleaned your bone with a sponge, soap and water, wipe it dry; then dip the soap in clean soft water, and wetting also the bone, rub the soap lightly over it, until the surface is lightly covered all over; then proceed to set in the usual way, keeping the soap sufficiently moist, and adding from time to time a little more soap and water, if it should be found necessary. Observe that the soap is clean and free from dust before you rub it on the bone; if it is not so it is easily washed clean. Strap the razor after setting, and also again when you put it by, and sponge the bone when you have done with it.—*Tillock's Philosophical Magazine.*

New Green Color.—Mr. Charles M. Willich, of London, in a letter to Dr. Tillock, says "I formed a strong decoction of tobacco by boiling it for some time in pure water; then added solution of sulphate of copper, [copperas] and precipitated with sub-carbonate of potash [potash of commerce.] The precipitate, when dry, is of a light green color. Mixed with linseed oil it became darker and brighter, and very like a rich green grass. Dissolved in nitric acid it forms a green solution. It also tinges sulphuric acid of a green color. I do not find that it is acted upon either by water, alcohol or ether. Mr. Tillock adds that he had been favored with specimens of this new green, both dry and

mixed up with linseed oil—that it is a most beautiful color, and will probably prove highly useful in the arts.

Preservation from Lightning.—Sir Humphrey Davy, in his fourth lecture at the Royal Institution, recommends the following means of escaping the electric fluid during a thunder storm. He observed that in countries where thunder storms are frequent and violent, a walking-cane might be fitted with a steel or iron rod to draw out at each end, one of which might be stuck in the ground, and the other end elevated eight or nine feet above the surface. The person, who apprehends danger, should fix the cane and lie down a few yards from it. By this simple apparatus, the lightning descends down the cane into the earth, and secures him from injury.

NEW ENGLAND FARMER.

SATURDAY, SEPTEMBER 13, 1823.

Subscribers who have not paid for the first vol. of the Farmer, are requested to forward us the amount due immediately; and those who wish to save 50 cents must pay for the second vol. by the 1st of October.

COMMUNICATION.

MR. EDITOR.—Much has been said in your valuable paper in regard to the use of Lime as a manure. You will greatly oblige me by stating in your next paper whether Lime mixed with common sea ooze, or mud, will make a manure for top dressing, and if so, in what manner it should be done?

Is Lime alone a good top dressing for grass seed? and if so, in what quantities and at what seasons of the year should it be applied?

Yours, A SUBSCRIBER.

ANSWER.

Sir John Sinclair informs us in his Code of Agriculture, page 24, of the Appendix, that "Sea Sleech [sea ooze] is of a most enriching nature, and adds to the staple of the soil. It is used as a top-dressing in spring, for crops both of grain and grass, more especially for the latter. It is an excellent material for composts, particularly for thin soils." Sea sand is likewise recommended by the same and other writers as a good ingredient in composts, and quick lime is always considered as the most important ingredient in composts, especially when any kind of earth composes another of its ingredients. If the compost is intended for a sandy soil, sea ooze would be best; if for a clay soil or stiff loam, sea sand should be preferred. We believe that sea ooze would make a good top-dressing without lime, but would generally be better with lime. Try it both ways. Quick lime applied as a top-dressing to grass, without any mixture, would scorch it, and so would lime water, according to Sir H. Davy. Therefore quick lime alone should not be spread on grass land with a view to an immediate increase of the crop of grass. Mr. Arthur Young, in his prize essay on manures, says, "lime should be spread on a layer [of grass] one full year before ploughing, that it may have time to fix itself firmly on the sward. If ploughed too soon it falls to the bottom of the furrow, and will be the sooner lost; for it continually sinks. The same observation has been made in Perthshire; they do not plough till it has taken a firm grip of the ground.—The same was the result in Lancashire. Three years before breaking up a ley [a piece of grass ground] part was limed with three hundred bushels an acre; and another part only one year before; the former produced ten for one of the seed; the latter six for one."

Indeed it is obvious to common sense as well as to sound philosophy, that you should not apply quick-dressing lime to any green and growing plants unless you wish to destroy them. Quick lime made into compost with several times its bulk of earth, well mixed, and suffered to remain a few days that its acrimony may be blunted, will be a safe and beneficial application to wheat; and no doubt would be of service to grass. Before using quick lime as manure let the cultivator ask himself this question: Would red hot cinders be injurious if used in the way I am about to employ hot lime? If so, let him cool his hot lime by mixing it with some substance proper for that purpose, or exposing it to air, or water, or both. He may scath hot cinders on a naked fallow, and so he may hot lim, but he should recollect that it will take longer to cool the latter than the former. And he may spread hot cinders over moss, peat, brakes, or other useless or pernicious vegetation; or he may use hot lime for the same purpose, but the hot lime will be the most efficacious as a burning substance, because it will give off a more lasting heat.

We would wish those who use lime as a manure to be aware of its efficacy because it produces no immediate beneficial effect. It must become perfectly mixed before it will be serviceable as a manure. Quick lime by a long exposure to the atmosphere, imbibes an excess of carbonic acid (fixed air) and becomes what chemists call a hyper-carbonate. "It unites with carbonic acid floating in the air, and when there is scarcity of aliment in the soil, it seizes and secures it from the atmosphere, and afterwards dispenses it according to the calls and necessities of vegetation."

* See N. E. Farmer, vol. ii, p. 42.

An Enemy to the Agricultural Interest.—A friend the Editor informs that many of his potatoes have, this season, been devoured by a LARGE WHITE WORM, with a red head, that eats into potatoes, particularly in land, and leaves many of them completely hollow with scarcely any integument except the pellicle remaining. The worm, he says, is commonly called *wick worm*, and is often found in door yards on half rotted chips, &c. If any of our friends or correspondents would give us further information relative to this insect, and point out some means of destroying or guarding against its ravages, they might benefit public, as well as oblige the Editor.

FOREIGN.

Spain.—The last accounts from Spain would lead to believe that the Spaniards do not mean to yield the right of self-government to foreign intermeddlers without at least achieving something worthy of the cause in which they are engaged. On the 16th of June they made a rally from Cadiz, which the Spanish Czar has thus officially described: "The entrenchments and parapets of the first line of the besiegers were captured by main force by our soldiers, and the resistance of the enemy, which was fruitless, cost him 4000 men. Our troops drove the French before them, and compelled to advance, trampling on the French dead, on the object of our rally being accomplished, I caused the return to be sounded. It was not expedient to give the enemy time to bring up his cavalry, a kind of force which we want. Our gun-boats rendered the most important assistance by the skilful fire which they kept up. All the troops maintained the best order and discipline, and displayed the greatest bravery. Cassano, who was severely wounded and taken by the enemy, was treated with a ferocious barbarity, which gives the lie to the pretensions to generosity and nobleness of conduct, which the French advance in the mountains bullfights."

An extra gazette, published by the Spaniards, states that "the French acknowledge their loss in the engagement to be 500 men, while, however, they re-

DRAMATIC ANECDOTE.—From the *Itinerant*.
MRS. JORDON.

The late Mrs. Jordan possessed a heart susceptible of the most tender and humane emotions, and these were called into instant action by the least approach of misery and distress. During her short stay at Chester, where she had been performing, her washer woman, with three small children, was, by a merciless creditor, thrown into prison. A small debt of forty shillings had been worked up, in a short time, by law expenses, into a bill of eight pounds. As soon as Mrs. Jordan heard of the circumstance, she sent for the attorney, paid his demand, and with as much severity as her good natured countenance could assume, said, "you lawyers are certainly infernal spirits sent on earth to make poor mortals miserable." The attorney, however, pocketed the affront, and with a low bow, made his exit.

On the afternoon of the same day the poor woman was liberated. As Mrs. Jordan, with her servant was taking her usual walk on the Chester walks, the widow with her children followed her; and just as she had taken her shelter from a shower of rain in a kind of porch, dropped on her knees, and, with much grateful emotion, exclaimed, "God forever bless you, madam! you have saved me and my family from ruin." The children beholding their mother's tears, added, by their cries, to the affecting scene; which a sensible mind could not behold without strong feelings of sympathy. The natural liveliness of Mrs. Jordan's disposition was not easily damped by sorrowful scenes; however, though she strove to hide it, the tears of feeling stole down her cheek, and stooping to kiss the children, she slipped a pound note into the mother's hand, and in her usual playful manner, replied, "There, there, now it's all over; go, good woman. God bless you—don't say another word." The grateful creature would have replied, but this good female Samaritan insisted on her silence and departure.

It so happened that another person had taken shelter under the porch, and witnessed the whole of this interesting scene, who as soon as Mrs. Jordan observed him, came forward, and holding out his hand, he exclaimed with a deep sigh, "Lady, pardon the freedom of a stranger, but would to the Lord the world were all like thee!" The figure of this man bespoke his calling; his countenance was pale, and a suit of sable black rather the worse for wear, covered his tall and spare person. The penetrating eye of Thalia's favorite votary soon developed his character and profession, and with her wonted good humor, retreating a few paces, she replied, "No, I won't shake hands with you!" "Why?" "Because you are a Methodist preacher, and when you know who I am, you'll send me to the devil?" "The Lord forbid! I am, as you say, a preacher of the gospel, which bids us to clothe the naked, feed the hungry, and relieve the distressed; and do you think I can behold a sister cheerfully obeying the commands of my great Master, without feeling that spiritual attachment that leads me to break through worldly customs, and offer you the hand of friendship and brotherly love?" "Well, well, you are a good old soul I dare say, but—I don't like fanatics; and you'll not like me when I tell you who I am." "I hope I shall." "Well then, I

tell you I am a player;" the preacher sighed; "yes—I am a player; you must have heard of me—Mrs. Jordan, is my name." After a short pause, he again extended his hand, and with a complacent countenance, he replied, "The Lord bless thee, whoever thou art; he has bestowed upon thee a large portion of his spirit; and as to thy calling, if thy soul upbraid thee not, the Lord forbid that I should."

Thus reconciled, and the rain having abated, they left the porch together; the offer of his arm was accepted, and the female Roscius of comedy, and the melancholy disciple of John Wesley, proceeded arm in arm, to the door of Mrs. Jordan's dwelling. At parting, the preacher shook hands with her, saying, "Fare thee well sister; I know not what the principles of thy calling may be, thou art the first I ever conversed with; but if their benevolent practice equals thine, I hope and trust, at the great day, the Lord will say to each:—*Thy sins are forgiven thee.*"

Vocal Music.—Considering myself as having a tolerable voice, and in my style, something of a knack at singing, you must not be surprised that I should most religiously believe that I can spend my Sundays to no better advantage than attending meeting, and assisting in the psalmody. But I would be glad to drop a word to you on my troubles. The young blades of our society have grown so much wiser and more learned than their fathers, that they clean out-run me. They have learned what they call their new city mode of soloing, trilling, judging, and quavering, that when I attempt to sing I am quite at odds with them.

This they call the new fashions—and our minister says he cannot preach against it for fear of giving offence. They must be indulged because they have learned it from their new city masters. After all, I really think, that when my wife and I, and Deacon Snigger's daughter Patience do not help them, especially on rainy days, their singing, as aunt Lucy says, "is sadly out at elbows."

I must tell you how we got served the other Sunday. Our good minister chanced to read one of our favorite psalms, beginning

With reverence let the saints appear,
And bow before the Lord;

When instead of singing the good old tune of *Mear*, and giving it the truly sonorous twang of New England, with which we used to sing at *Tun-ton*, our young blades galloped off in a new city tune, slurring away in a most delectable quaver;

With reverence let the sa—a—aints appear,
And bow—wow—wow—before the Lord!

This was unlucky slurring; for our minister's little whiffet pug happening to catch the note, sang out his trouble pipes, started the squire's old towzer's full bass, and in an instant the whole posse of dogs set up such a chorus, that our meeting would have been deafened by the general yell, had not our worthy sexton by his cane changed their notes to another key, and sent their quavering out of the door. Deacon Goodspeed, who happened at that time to be comfortably dozing in his seat, rolled up the pooled eniums of his eyes, and our good minister was obliged to hide his head and smother a smile.—*Oxford Gazette.*

from a London paper.

Jasmine.—We are told that a Duke of Tuscany was the first possessor of this pretty shrub in Europe, and he was so jealously fearful lest others should enjoy what he alone wished to possess, that strict injunctions were given to his gardener not to give a slip—not so much as a single flower, to any person. To this command the gardener would have been faithful had not love wounded him by the sparkling eye of a fair but portionless peasant, whose want of a little dowry and his poverty alone kept her from the hymeneal altar. On the birth day of his mistress, he presented her with a nosegay, and to render the banquet more acceptable, ornamented it with a branch of *jasmine*. The *Povera Figlia*, wishing to preserve the bloom of this new flower, put it into fresh earth, and the branch remained green all the year. In the following spring it grew, and was covered with flowers: it flourished and multiplied so much under the fair nymph's cultivation, that she was able to amass a little fortune from the sale of the precious gift which love had made her when with a sprig of *jasmine* in her breast she bestowed her hand and wealth on the happy gardener of her heart. And the Tuscan girls this day preserve the remembrance of this adventure by invariably wearing a nosegay of *jasmine* on their wedding day; and they have proverbs, which says, a young girl worthy wearing a nosegay is rich enough to make the fortune of a good husband.

The Duchess of Devonshire.—As the beautiful Duchess of Devonshire was one day stepping out of her carriage, a dustman, who was accidental standing by, and was about to regale himself with his accustomed whiff of tobacco, caught glance of her countenance, and instantly exclaimed, "Lord love you my lady, let me light a pipe in your eyes!" The Duchess was so delighted with the compliment, that she frequently afterwards checked the strains of adulation which were so constantly offered to her charm by saying, "Oh! after the dustman's comment, all others are insipid."

The manner in which the eagle will sometimes attack oxen in Heligoland, is very singular. It plunges itself into the waves, and after being completely drenched, rolls itself on shore, till its wings are quite covered with sand; it then rises into the air and hovers over its victim. When close to it, it shakes its wings and throws stones and sand into the eyes of the ox while it completes the terror of the animal with blows with its powerful wings. The blinded ox runs about quite raving, and at length falls down wholly exhausted, or dashes himself to death falling from some cliff. The eagle then makes glides undisturbed the fruits of his victory.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within *sixty days* from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrears are paid.

Agents who procure seven subscribers, and become responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

FARMER'S AND GARDENER'S REMEMBRANCE.

[BY THE EDITOR.]

ADDITIONAL REMARKS ON FOOD FOR SWINE. In our last paper (pp. 19, 50,) we went somewhat at large into the consideration of the different kinds of food for swine, and the different modes of preparing such food, without attention of continuing or soon resuming the subject. But some further information, concerning these topics, having since occurred to which may lead to practical results of some utility, we proceed to place it before our readers.

An English farmer, whose observations are well approved in Monk's Agricultural Dictionary, says "from an accurate experiment the last year, I dare venture to recommend baked potatoes as an excellent food for hogs, pork, produced by this food, was equal to that of barley and beans; but at present I cannot exactly ascertain the comparative experiment with regard to expense; however, I am of opinion that roasted or baked potatoes, containing the improvement of the hogs, is as good a food, if not cheaper than can be given. I roast my potatoes on a kiln similar to that used by oat-meal shellers for drying oats. The action of the fire, by dissipating the crude juices that are contained in raw ones, reduces them to a state highly whole and nutritious. Boiling does this in part, but so effectually. A potatoe roasted in the manner thus described partakes much of the quality of a chestnut, and perhaps is not greatly inferior to it."

In the 4th Vol. of Communications to the Editor of Agriculture, p. 296, contains a long article on "Baking Potatoes" together with a list of an oven for that purpose, by Mr. W. Pierpont. Mr. P. says "Potatoes cured by fire are not so apt to turn sour, or scum the more they are dry, so that the animal feed them drinks a deal more, and they become hard when cold, so as to be flung to the waste with more convenience than when steamed. They were used chiefly, in fattening neat and sheep. But pigs were likewise fattened with baked potatoes, and the pigs were fattened, particularly the fat. The pigs towards the latter end a few whole peas each meal." The oven for baking the potatoes, used by Mr. Pierpont, was of cast iron, a brick furnace in such a manner as to be heated by the flame at the bottom and three sides. The potatoes were placed in vessels digested: which digesters "must be in contact with the fire, and even when on cast iron must have legs so that they do not touch the cast iron. These vessels must have lids, steam tight, with valves, and the potatoes are done in reason the

writer in the Bath papers, vol. iii, p. 296,

the volume from which this is extracted (as referred to) may be found in the Library of the Massachusetts Agricultural Society, and may be profitably read by any person who contemplates feeding other animals with potatoes on a large scale.

says "Potatoes should be dressed in an iron pot over a slow fire, without any water than what the fire will gradually extract from the root itself. By this mode they are far more dry, mellow and rich than when any other water is added to them." We should suppose that this mode of cooking potatoes would be about equivalent to baking or roasting. Indeed we do not perceive why potatoes placed in an iron pot over a tolerable brisk fire without water, should not be baked instead of boiled; but, perhaps if the top of the pot is covered so as to confine the steam rising from the potatoes, and the fire is quite moderate, they might be boiled in their own liquor. Experiments on this subject may be very easily made, and there can be no doubt but the driest modes by which potatoes can be cooked, will be the best, provided the expense of cooking them is not enhanced by such modes, and we can avoid the risk of scorching or burning the potatoes.

If your object is merely profit in fattening your hogs you must take time for the process, and thus make them thoroughly fat. A farmer stating the result of some experiments in the Bath Society papers, vol. vi, p. 332, says, "I invariably found that the quantities of food consumed [by fattening hogs] increased every week, till the animal became three parts fat; after this period they ate but little; and almost all they ate turned to fat. It is, therefore, good policy to make them completely fat; and that can only be done by giving time." Very fat meat, however, is less palatable, and less wholesome for common family consumption than that which is less fat; but it will, we believe, commonly command a higher price in market, and is to be preferred for many uses.

We have alluded (p. 50) to some apparent differences of opinion amongst agricultural writers on the subject of making food *sour* for fattening swine; and expressed our apprehension that the wash might be injured by making it too sour. We have, since that was written, perused a communication addressed to the Hon. Richard Peters, President of the Pennsylvania Agricultural Society, written by J. P. De Gruchy, who appears to have been well acquainted both with the theory and practice of this branch of rural economy. This gentleman says "I differ with you, with respect to *sour* wash being the most grateful and alimentary to swine. In England I know such an opinion prevails; but in this climate I am certain, mine *est mos*, and *thrice best* while it is *sweet*." To this Judge Peters replies, "My experience has uniformly been favorable to the *sour* wash both for health and economy; much less grain or meal will suffice; and its fermentation with water fixes the saccharine quality so essential to nutrition." The first or saccharine state of fermentation in grain or meal substances, *generates* sugar, or converts the starch in the fermenting substance into sugar; but if the process of fermentation proceeds rapidly, it is probable that all the sugar will not be developed before the wash begins to turn acid, and therefore there will be most sugar (which is the substance wanted) in the wash, at the time the acetous fermentation

commences. This period will, therefore be the proper time to use the wash for feeding hogs or other animals. This position may be illustrated by what some writers call the *puante fermentation*, or that process of nature, by which dough is fermented so as to become most suitable for making bread. The precise time when bread should be put in the oven is when it has undergone such a degree of fermentation as to correct the heaviness and insipidity of the flour, or has arrived at the first degree of acidification. And if the dough was intended to feed swine, it should be given them in that state of its fermentation when it would make the best bread. If it becomes decidedly acid it has lost a part of its nutriment, and has begun to be dissolved into its original elements. An analogous period in the fermentation of a wash should, we think, be chosen for feeding swine with it. And this period will be while it is yet full of fixed air, sweet, palatable, but slightly acid, or beginning to be sour.

But the question whether *sweet* or *sour* wash is most grateful to swine would be more correctly decided by pigs than by philosophers.—Place before your swine several washes in different vessels, but the mashes made of the same materials, say Indian meal with mashed potatoes and water. Let wash No. 1 be perfectly fresh; No. 2 in the saccharine stage of fermentation; No. 3 slightly acid; and No. 4 completely soured, and leave it to the hogs to settle the dispute so far as respects what kind of wash is most grateful to the taste of those animals; and we believe the kind which they prefer will prove most "alimentary;" or nourishing and wholesome, as well as most wholesome. It is said to be foolish to dispute about the tastes of human beings (*de gustibus non est disputandum*) and it is surely much greater folly to dispute about the taste of a hog, when the animal is ready to decide for himself. Perhaps, however, a change of diet, as regards sweet or sour food, may prove useful, and if hogs are found to prefer the former, yet now and then an acid mess may give an edge to their appetites; or if food a little sour is best for their general consumption, now and then a sweet mess may be given for the sake of variety.

There is a species of fermentation of grain highly recommended by some foreign agriculturists, as useful in preparing food for swine, which may perhaps in some instances be adopted by the American farmer. We allude to *melting* grain, which is often done in England, to feed pigs and poultry. We do not believe that farmers in general, (even if we should recommend it) will be at the trouble and expense of sending their grain to a maltster for the purpose above mentioned, but perhaps some persons may be induced to adopt that part of the process of malting which increases the nutriment of the grain. They may soak their peas, Indian corn, &c. till it begins to sprout, by which means saccharine matter will be developed, and either give it to their hogs while moist, dry it in a kiln, or spread it thin and expose it to the sun till perfectly dry, when it may be kept in the granary, and used when wanted.

It is said that hogs thrive best when there are but three or four in the same apartment of a pen. They are fond of society, but are apt to degenerate into a "swinish multitude," and become exceedingly riotous if congregated in a large assembly. As they know no law, and acknowledge no right but the right of the strongest, they sometimes condemn a weaker brother in a popular assembly, as the Athenians did Socrates, and proceed to execute him without judge or jury. The sty, therefore, should have a number of apartments separated by close partitions, and there may be a general feeding trough, to which each division of animals may have separate access.

The experienced farmer need not be told that fitting hogs should have now and then a dose of brimstone and antimony given with their food, in order to preserve their health and increase their appetite. But there may be some who never knew, or do not remember, that rotten wood thrown to them occasionally will be devoured with avidity, and serve as an absorbent of acrid juices, which might otherwise occasion a disorder which, in human subjects, is called dyspepsia, or indigestion. It is likewise said that to throw them now and then a few pieces of charcoal will answer the same purpose. At any rate, those substances can do no harm, and if the swine have an appetite for them they will doubtless prove beneficial.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—A writer in your paper, vol. 2, p. 6, states that he has heard of a cure for poison on the skin, but does not know it to be effectual. I will state to you one which I discovered by accident, and which I have practised for myself and work people, for years, when poisoned, and with the best success. It is to wash the parts affected with weak lye; if this is not at hand I have sometimes dissolved a little saltpetre in cold water, and had it produce the same beneficial effects. I always make the application as soon as the poison makes its appearance. How this treatment would do in an advanced stage of the disease, I am unable to say, having never had occasion to try it.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR—Having, within a few years, seen stated in the public prints, several opinions respecting the salivation or slavers of horses and none of them being satisfactory to me, I will submit to you some particulars that have fallen under my observation. For some years past I have been convinced that the slavers of horses is caused by their eating a kind of grass of second growth, making its appearance in the fore part of July, much resembling oats, which come up in fall after the crop has been taken off the ground, but has rather more of a brownish cast, and retains its green very late in the fall. When chewed it causes a flow of water in the mouth more than any other vegetable that I have ever seen. If it has such an effect on man, why should it not have on horses?

There is another kind of grass that can scarcely be distinguished from it otherwise than by tasting.

It is, I think, but about 20 or 25 years since there was any such disorder among the horses

in this part of the country. Many escaped for some years after it had become common in the vicinity. The first I saw in my own horses, was in a horse that was turned into a small pasture, where one had seldom been before. In another pasture, on the same hill, about 10 rods distant, separated by a natural English mowing, there was no such effect produced. From this circumstance I was led to seek for the cause of the slavers. Some had supposed it to be Lobelia or Indian Tobacco; on examination, it appeared, that in the small pasture there was no Lobelia, in the other there was much of it; and in no instance have I been able to find a plant of Lobelia that appears to have been bitten off by cattle of any kind. This satisfied me that it was not the Lobelia.

After a few years it was the same with all my pastures that had never been ploughed, and at night when my cows were brought to the yard for milking, streams of water ran almost continually from their mouths. Some few years since, being short of English hay, but having plenty of rowen, instead of hay I had my horses fed with rowen. In a short time they had the slavers as bad as they had ever had them in the summer. Remembering where this rowen was grown, the next season, upon examination, I found there was a great quantity of the grass above described. This summer my horses were not afflicted with this disorder so early as formerly. Previous to their being affected with the disease, I could find none of this grass; since that time I have discovered some, though the quantity is small compared with former years.

From the above mentioned circumstances and facts, I am led to conclude, that the grass which I have described is the true cause of slavers in horses. I leave it for the examination of others, and to those more acquainted with diseases than I am, to prescribe a remedy.

LOVETT PETERS.

Westborough, Sept. 15, 1823.

From Letters of Agricola.

In the year 1306, I was one afternoon leaning over the grave of Burns, and reading the plain inscription on his tomb-stone erected in the church-yard of Dumfries. This town was the concluding scene of the Scottish Bard; and here terminated his follies and his crimes, the last breathings of his muse and of his life. I was indulging in one of those moods, in which pain and pleasure are so equally blended, that the mind is thrown into a sort of delightful melancholy: for while I retraced many gay and lively recollections, I was forced by present objects to check the rising emotions, and embitter them with grief. His enchanting and splendid verses were contrasted, in the eye of fancy, with the dark shades of his character; the strength and manly independence of his intellect with the silly and inconsistent waverings of his moral perceptions; the bright and promising morning of his life with the ominous and black cloud, which settled on the evening of his days. I was riveted to the spot; tears filled my eyes; my whole soul was absorbed in contemplation; it was a moment of rich enjoyment. A slow and faltering step struck my ear, and turning round I discovered an emaciated, but venerable figure approaching, in the last decrepitude of old age.

"Stranger, said he, you are paying the tribute of respect to the memory of our poet and I must beg pardon for this abrupt intrusion. There was such an air of good nature in that old man, heightened by the sense of his belatedness, that I addressed him frankly in reply and showed no reluctance to engage in conversation. He sketched to me, with all the loquacity characteristic of his years, the habits, the faults, the drunken broils of the man, who at the same time he appeared an ardent admirer of the faithful coloring, the playful wit, the winning sprightliness of the writer.

"Come, said he, along with me to the hills where Burns alternately brutified his senses, exalted them by the varied inspirations of 'lyre.' I accompanied him, and we ascended together the mound of earth, on the top of which is the seat—once the favorite haunt of this immortal and extraordinary genius; a like remarkable for witnessing his fits of intoxication, and in favored intervals, his effusions of poetic rapture. It is still shown to the curious lies within the precincts of the town, and commands a fine prospect of the surrounding country. We seated ourselves on the grassy tuft and grown familiar by an interchange of sentiment, we conversed on the most intimate footing. From Burns we soon passed to other topics, possessing novelty or interest.

"The country, said I, in every direction around, and wherever I have travelled, is mostly arable, and highly cultivated. The red and white wheats prevail universally, and are so seemingly by the farmers in equal quantities."

"Yes; replied the old man, there is a wonderful change in this district, since I was of your age; for I can recollect the time, when there were neither enclosures nor wheat in all that country."

"Is it possible, I answered, that all these improvements are of so recent a date, as to be within the reach of your remembrance? I should like, if you would relate to me the ancient state of the country, the condition of the tenants, and the progress of agriculture."

That I shall do with all my heart, rejoined my acquaintance, his eyes brightening as he spoke; for like myself he seemed fond of the subject.

I was born, continued he, in 1719, in Lochmaben, and am now 37 years of age. The old thing I recollect, is the great riot which took place, throughout the whole of this shire, in 1721, in consequence of the landed proprietors beginning to enclose their estates on purpose stock them with black cattle. The small tenants were turned out, to make way for this improvement; and the ground was fenced by sunk ditch and wall, called then park-ditch. Great distress was felt in the country on account of this alteration; and the tenantry rose in mob, and with pitchforks, spades, and mattocks proceeded to level all these enclosures, from one end of the country to the other. My father was unfortunately concerned in that turbulence; and after it was quelled by the help of two troops of dragoons brought from Edinburgh, he was banished to the American plantations for his crime. I lived afterwards, as was brought up with my uncle in Nightdale, about 20 miles hence, who rented there a small farm of about 100 acres, and assisted him in working it. The general produce of all the

country was grey oats; although the gentlemen their croft or best land raised also a little bar or bigg, and some white oats; yet the soil was by all men believed incapable of raising wheat; and accordingly it was never tried. Our common food consisted of these grey oats parched, or burnt out of the ear and ground in a hollow stone by the hand; of milk; of *kail; of oats; with never more than one ewe killed Martinmas for the family. The houses were generally built of mud and covered with thatch; the clothing was of flaxing—a coarse knitted stuff manufactured at home, from the black and white wool mixed together. Hats and shoes were only worn by the gentry; and when they often appeared at court with a coat and their wives' making. Potatoes were not introduced till 1725, and at first were cultivated with much care, and in small patches. They were carried to the great towns on horses backs, and retailed at an high price by pounds and ounces. It was about the year 1735, when they came into common use, and before that period, there was often great scarcity of food, sometimes bordering on famine in this fine country, which was then accounted incapable of raising bread for its scanty population. Dumfries at present contains more inhabitants than were in the whole county; and 20 acres are now more productive than 200 in those days, which was the low state of husbandry, that the principal supply came from Cumberland, on the other side of the Esk; and I myself have witnessed on the Wednesdays, which from time immemorial have been our market days, scenes of real distress occasioned by the swelling of the river, which prevented the carriers in bringing forward the meal; as the want of bridges often interrupted all communication. I have seen, proceeded the old man with greater animation, and pointing with the staff in his hand, all that country before us covered and overgrown with twines and broom, and not a single vestige of these hedges and stone walls which cross and intersect the whole landscape. Few sheep and black cattle picked the scanty herbage; and they were prevented from eating; growing corn, either by a herd-boy who tended them, or by a temporary fence erected every year. The common people very often collected nettles in the field, of which they made kind of coarse soup thickened with oatmeal, and enriched, on great days, by a piece of butter as a luxury. The state of Scotland from my youth up to 175 was miserable in the extreme; the lower classes were ill fed, ill clothed, and languid; and there was no revival in their circumstances till the introduction of potatoes and lime.

Of potatoes and lime, repeated I; I can perceive some reason, why the first should improve their condition, but what connexion had the last with it?

Lime, continued my instructor, operated with much more success on the prosperity of the country than potatoes; and I look upon it as the friend we ever saw.

Explain yourself, said I; for all this seems mysterious, and I cannot conceive, how lime could have wrought such enchantment.

To your satisfaction, then, I shall account for

it; and my present views have not been altered for the last 20 years of my life. Seventy years ago, in 1738, there was no lime used for building in Dumfries, except a little made of cockle shells, burnt at Colvend, and brought on horses backs a distance of twenty two miles. All the houses were either composed of mud walls, strengthened by upright posts and these bound and connected together by wattled twigs; or they were built of stone laid, not in mortar, but in clay or moist loam. The whole town was a collection of dirty, mean, and frail hovels, never exceeding one story; because the materials had not strength or firmness to bear more. These buildings were so perishable, and stood in need of such constant propping, that people never thought of expending time, labor, and money on the comforts of a habitation, which was to fall into ruins during the course of their lifetime. Old Provost Bell's house, which was founded in 1740, is the only one now remaining of the ancient town; and although the under-story was built with clay, the two upper were laid in lime which is the cause of its long-standing. Between the years of 1750 and 1760, the old mud walls gave place to those of stone laid in mortar; and from that period, there has been a visible and rapid improvement. Houses acquired permanence, descended from father to son, and the labors of one generation were enjoyed by the next. To lime, then, we owe these stately edifices, with all the comforts and conveniences they confer: and it hence contributed, in a remarkable degree, to the refinement and polish of private life.

If to this fossil, continued the old man, we are indebted for the stability of our towns, we are under greater obligations for its unprecedented effects on the powers of the earth. Wheat and clover would not thrive in the county of Dumfries, or in the Stewartry of Kirkcudbright, till lime was plentifully incorporated with the soil; and after its introduction, the farmers became rich, land advanced in value, the produce was multiplied tenfold, population increased, and these counties quickly rose to their present unexampled prosperity. In my younger days, it cost much toil to raise on my uncle's farm 2 or 2½ bolls of grey oats per acre, and after taking one or two crops, the ground lay for four or five years in natural grass, which was coarse and unpalatable to the cattle. The rent—only 2s. 6d. per acre—we found great difficulty in scraping together, and we fell on a thousand shifts to accomplish it. Now, the same farm is rented at £3 10 per acre, is kept under constant cropping, rears excellent wheat, is wholly drained and enclosed, supports a genteel family in all the comforts of life, and one year's rent of it is double the sum, which could have purchased it altogether 65 years ago.—It is lime, that has warmed and meliorated the soil, that has endowed it with productive powers, and that supports all the plenty and prosperity you have been admiring, as you travelled through the district. He paused; I looked in his face, and a glow of animation had overspread the paleness of age. His right hand was extended in an impressive posture, and his left rested on his staff. The pencil of Titian could not have done him half justice. I rose and bowed; we came down together, and I retired to my apartment in the inn, to note down the particulars of this interesting conversation.

From the Claremont (N. H.) Spectator.

New Threshing Mill.—On Friday last a number of gentlemen of this town, and Windsor, Vt. witnessed the operations of a Threshing Mill, invented by Messrs. Tylers and Andrews of this town; and the result of several experiments satisfied all present that it would thresh and clean fifteen bushels of wheat in an hour. The labor of threshing and cleaning is performed in the most perfect manner—not a kernel of wheat could be found in the heads, after passing through the Mill. Every particle of dust and chaff is separated from the grain and blown away, and the straw is cut into pieces about four inches in length. This Mill has been used with equal success, in threshing Clover-seed, Rice, and Coffee. The machine is kept in motion by two horses, and requires a driver and four men to tend it. Messrs. Tylers have been engaged for three or four years past, in perfecting their design; and while we congratulate them on their success, we hope their ingenuity and perseverance will be liberally rewarded, for having made so valuable an acquisition to the useful inventions of our country.

Since the above was in type, we have learnt that Messrs. Tylers and Andrews made another trial of their Threshing Mill, on Monday last; when they threshed and cleaned four bushels of wheat in nine minutes; which is at the rate of twenty-six bushels and two thirds in an hour. The cause of this difference in the two experiments, we understand arose from a difference in the horses; one of those employed in the first instance, being a bad one. Water or steam power may be applied with increased advantage.

From the Baltimore Republican.

The crops.—In Virginia and Maryland, the recent crops have been unusually abundant—and thanks to a beneficent Providence, the growing one promises to be peculiarly so. At Richmond on the 26th ultimo, corn, which a fortnight previous was selling at three dollars a barrel, had fallen to 1.90 a 2—meal was 75 cents a bushel, and a strong probability of its being still lower. The rains of the present month have had the happiest effect, and brightened the prospects of the planter. To the south, finer crops of corn have seldom been seen. In the two Carolinas, Georgia and Alabama, the earth is loaded with her productions.—Corn sells at 25 and 30 cents a bushel, in Georgia.—In Maryland the crops have been unusually prolific. Rye, Oats, Flax, Hay, Wheat and Corn bid fair to exceed the most sanguine expectations of the farmers in many parts of our state. While contemplating these cheering agricultural prospects, our hearts dilate with gratitude, to the "Giver of every good and perfect gift."

Mrs. G.'s Famous Buns.—One pound and a half of flour, (a quarter pound left to sift in last) and a half pound of butter cut up fine together; then add four eggs beat to a high froth, four tea cups of milk, half a wine glass of brandy, wine, and rose water each, and one wine glass of yeast; stir it all together with a knife, and add half a pound of sugar, then sift in the quarter of a pound of flour, and when the lumps are all beaten fine, set them to rise in the pans (they are to be baked in). This quantity will make four square pans full.

* A species of greens used in Scotland for broth, and called Colwort.
† Furze.

DESCRIPTION

OF MR. PERKINS' STEAM ENGINE, AND
From the Edinburgh Philosophical Journal.

We have already communicated to our readers in the two last numbers of this Journal, all the authentic information which we could obtain respecting Mr. Perkins' new Steam Engine; and we have used the utmost diligence to obtain such further information as may, in some measure, gratify that curiosity which these imperfect notices have excited. There has never been in our day an invention which has created such a sensation in the scientific and in the manufacturing world. The steam engine of Mr. Watt had been so long considered as the greatest triumph of art and science, that it was deemed a sort of heresy to regard it as capable of improvement; and notwithstanding all that has been done by Mr. Woolfe, and other eminent engineers, the undoubted merit of their engines has scarcely yet been admitted by the public. Under such circumstances, Mr. Perkins' claims were likely to meet with various kinds of opposition. Instead of bailing it as an invention which was to do honor to the age in which we live, and to add a new and powerful arm to British industry, imperfect experiments and confined views were urged against the principle of its construction, the jealousies of rival traders were arrayed against it, imaginary apprehensions of danger were excited, and short-sighted politicians sounded the alarm, that such an invention would precipitate our country from its lofty pre-eminence among the manufacturing nations of the world.

Most of these grounds of opposition have been now removed by direct experiment. Mr.

PERKINS' engine is actually at work. Its operations have been witnessed, and minutely examined by engineers and philosophers of all kinds; and the most unreasonable sceptics have been compelled to acknowledge the justness of its principles, as well as the energy of its operations. The active and inventive mind of Mr. Perkins, however, did not remain satisfied with this experiment. He has discovered a method, which we consider equal in value to his new engine, by which he can convey the benefit of his original principle to steam engines of the old construction; and this has been recently succeeded, we are told, by a most extraordinary discovery, that the same heat may be made to perform its part more than once, in the active operations of the engine.

In order to convey to our readers some idea of these great inventions, we have obtained a drawing, made by M. Montgolfier, Jr. which though it does not represent the actual machine, yet contains such a view of its parts as is necessary for understanding its principle.

The generator, which supplies the place of the boiler in ordinary steam engines, is a cylinder A B C D, made of gun metal, which is more tenacious, and less liable to oxidation, than any other. The metal is about three inches thick; and the vessel, containing eight gallons of water, is closed at both ends, with the exception of the five openings for tubes, shown in the figure. The generator is placed vertically in a cylindrical furnace E F, whose chimney is G, the heat being sustained by a pair of bellows H, wrought by the engine, and conveying its blast

in the direction I K to F. A heat from 400 to 450 degrees of Fahrenheit is thus applied to the generator which is entirely filled with water. The valves in the tubes m, n, which are steel cylinders working in hollow steel pipes are loaded, the one with 37, and the other with 35 atmospheres; so that none of them can rise till the heat creates a force greater than the least of these weights.

Let us now suppose, that, by means of the compressing pump L, whose handle M is wrought by the engine, water is forced into the generator; this opens the valve above n, loaded with 35 atmospheres, and instantly a portion of the heated and compressed water flashes out in the form of steam of high elasticity, and of a temperature of 420 deg. and communicating by the steam pipe 2, 2, 2, with the valve box V, it enters the cylinder P P, lying horizontally, and gives motion to its piston P Q which performs 200 strokes in a minute, and drives a crank R, which gives a rotary motion to a fly-wheel, as seen in the figure.* When the eduction valve is opened, the steam, after having produced its stroke, is carried by the eduction pipe 3, 3, 3, into the condenser S T X U, where it is condensed into water at a temperature of about 320 deg. and under a pressure of five atmospheres, from thence, by the pipe 6, 6, 6, it is drawn into the pump L, whence it is forced along the

* The parallel motion represented at P Q, is not the correct one used by Mr. Perkins. The piston-rod is connected by a flexible joint, with a sort of carriage with four wheels at each end, and working in a strong horizontal box of steel.

4, 1, 4, to the generator, thus performing complete circuit.

The forcing pump acts with a pressure exceeding 35 atmospheres; consequently, when the steam received in it from the condenser is urged to the generator, it must expel a portion equal to itself in volume: this portion, as above described, flashes instantly into highly elastic steam. The forcing pump, too, is so contrived to act with a steady force, and, consequently, the expelled water must be driven from the generator in a steady current, and thus steam of constant elasticity is supplied to produce the power.

Some philosophers are of opinion that the weight of the portion of water which escapes is itself sufficient to maintain the steam at that degree of heat and elasticity with which it leaves the piston; and consequently that this is nothing more than a High Pressure engine. Other persons, however, have supposed, and we confess we are among that number, that the portion of water which escapes must necessarily carry off a quantity of heat from the boiling stratum (the temperature of which may be thus reduced below the freezing point.) It is more likely, that, in virtue of some law of the transmission of heat under combined conditions of elevated temperature and high pressure, while the water, also, is allowed to remain in contact with the red hot generator; the whole water in the boiler may indeed under requisition to furnish the discharge of fluid with its necessary supply of caloric heat.]

It is almost unnecessary to state, that the motion of the engine is produced by the difference of elasticity between the steam pressing on the inside of the piston and that pressing on the outside. In the first case, the steam recently produced, acts with a force, say of 500 pounds, on the square inch, while that on the weak side, or communicating with the condenser, acts with only 70; the difference, or 430 pounds, is the true power gained.

When there is a surplus of water in the generator, occasioned either by working the forcing pump too violently, or by too vehement a fire, the water will escape by the tube *m* with the valve above, loaded with 37 atmospheres, and will pass by the pipe 5, 5, 5, into the condenser S T X U.

In order to explain the ingenious manner in which the pipe 4, 1, 4, supplies the generator with water, we must observe that this pipe communicates with the pump *L*, which is actuated by the engine.

This pump draws the water by the pipe 6, 6, from the condenser S T X U, and returns it by the pipe 4, 4, 4; that is to say, when the valve *M* is drawn up, the water rushes into the cylinder of the forcing pump, through a valve in the pipe 6, 6, opening into that cylinder. This valve, of course, instantly closes on the downward stroke of the pump is made, and the water now escapes through a valve opening outwards along 4, 1, 4; thus effectually cutting off all direct or uninterrupted communication between the generator and condenser. In order to keep the water in the condenser at a pressure of five atmospheres, the blast of the steam goes round the condenser S T X U; when it is not sufficient for this purpose, the water is introduced from the reservoir *L*,

by means of the pipe 7, 7, 7, loaded with live steam.

From the high elasticity of the steam employed in this engine, it has been supposed to be very liable to explosion. This however is a vulgar error. Since there is no reservoir of steam exposing a large surface to its expansive force, as in the common high pressure engines, the steam being generated only in sufficient quantity to produce each succeeding stroke of the piston, the ordinary source of danger is entirely removed. But, in order to take away all apprehensions on that subject, the induction pipe 2, 2, 2, in which the steam is actually generated, is made so strong as to sustain an internal force of 4000 pounds on the square inch, which is eight times more powerful than the actual pressure, viz. 500 pounds on the square inch, with which the engine works. This enormous superabundance of strength is still further secured by means of the safety pipe, 3, 3, 3, provided with a thin copper "safety bulb," *a*, *b*, which is made so as to burst at a pressure of 1000 pounds on the square inch. In order to satisfy his friends on this very important point, Mr. Perkins has repeatedly urged the power of the steam to such a degree as to burst the copper bulb in their presence. This tube merely rends, or is torn asunder like a piece of paper, and occasions no injury either to the spectators, or to the apparatus; so that we have no hesitation in considering this engine, notwithstanding its tremendous energies, as much more safe in its operations than even the common low pressure engine.

The safety tube, 3, 3, 3, communicates also with the indication *c d*, having a dial-plate *c e*, and an index *e f*, which by means of a suitable contrivance at *v v*, indicates the pressure or number of atmospheres with which the engine is working.

The cylinder and piston P P Q, have been separated from the rest of the engine, for the sake of distinctness. Their proper position, however, will be understood by supposing the two lines 99; 99 to coincide, as well as the tubes 2, 3; 2, 3.

This engine which we have now described, is at present performing actual work in Mr. Perkins's manufactory. It is calculated as equal to a ten horse power, though the cylinder is no more than 2 inches in diameter, and 18 inches long, with a stroke of only 12 inches. Although the space occupied by the engine is not more than 6 feet by 3, yet Mr. Perkins considers that the apparatus, (with the exception of working cylinder P P, and piston P Q) is perfectly sufficient for a thirty horse engine. When the engine performs full work, it consumes only two bushels of coal in one day.

On the application of Mr. Perkins' principle to Steam Engines of the old construction.

Great as the invention is which we have now described, yet we are disposed to think that the application of the principle to old steam engines is not less important. The old engines, with their boilers, are retained unaltered. The furnaces alone are removed. Mr. Perkins constructs a generator consisting of three horizontal tubes of gun metal, connected together, filled with water, and supplied with water from a forcing pump, as in his own engine. This generator is exposed to heat in an analogous man-

ner, so that by means of a loaded valve, which opens and shuts, the red hot fluid may be constrained till forced out of the generator into the water in the boilers of Hadton & Watt. By this means, as much low pressure steam of four pounds on the square inch may be generated by one bushel of coals, as could be produced in the old engine by nine bushels. This most important result was obtained by actual experiment.

Since these great improvements have been effected, Mr. Perkins has made a discovery that seems, in its practical importance, to surpass them all. He now entirely dispenses with the use of the condenser, and works the engine against the atmosphere alone; and, by methods with which we are not acquainted, and which indeed it would not be prudent for him to disclose at present, he is enabled to arrest the heat after it has performed its mechanical functions, and actually pump it back to the generator, to unite with a fresh portion of water, and renew its useful labors. In an operation like this, a considerable portion of the heat must still be lost; but the wonder is that any should be saved; and we venture to say, that the most sanguine speculator on the omnipotence of the steam engine, never dared even to imagine the possibility of such an invention.

We are well aware, that, in announcing this discovery, we are exposing ourselves to the criticisms of those whose belief is naturally enough limited by their own experience; but it is satisfactory to know that Capt. Basil Hall, (whose account of Mr. Perkins' discoveries and inventions, as delivered before the Royal Society of Edinburgh, gave such universal satisfaction) has been entrusted with Mr. Perkins' discovery, and that he speaks confidently of the soundness of its principles, as well as the practicability of its application.

We cannot quit this subject without congratulating the country on the brilliant prospects with which these inventions promise to invest all our national concerns. At any period of the history of British industry, they must have existed in the highest reputation; but originating as they have done, when our commerce, our manufactures, and our agriculture, the three stars of our national prosperity, have just passed the lowest point of their orbit, and quitted, we trust, for long, the scene of their disturbing forces, we cannot but hail them with the liveliest enthusiasm, and regard them as contributing to ensure the preeminence of our industry, to augment the wealth and resources of the nation, and, by giving employment to idle hands, and direction to idle minds, to secure the integrity and permanency of our national institutions.

The London Journal of Arts, for July 1823, has been received. It contains several articles on the subject of Perkins' Steam Engine. It appears that our countryman had made application for three patents on the subject of his improvements and discoveries. The first passed the seal in Dec. 1822, the second was to be specified in November, and the specification of the third patent to be enrolled in December, 1823. The Journal adds,

"An engine (of which we believe eighty horse power) upon these improved principles, is in considerable forwardness, intended for the purpose of navigation; and there is great reason to believe

that before the close of the present summer, it will be in operation between London and Margate.

"The mode of generating steam is now fairly before the public, and from the unreserved frankness with which Mr. PERKINS has received many hundreds of visitors, there can be no wish on his part to shrink from philosophical investigation; the advantages proposed are no longer a speculative hypothesis, but a subject, the merits of which can be ascertained by experiment beyond all doubt."

NEW ENGLAND FARMER.

SATURDAY, SEPTEMBER 20, 1833.

[Subscribers who have not paid for the first vol. of the Farmer, are requested to forward us the amount due immediately; and those who wish to save 50 cents must pay for the second vol. by the 1st of October.]

Extracts from a work lately published by WILLIAM COBBETT, entitled "*Collage Economy*," with occasional remarks on some of the statements of the author.

[Continued from page 47.]

Mr. Cobbett diverges from the main branch of his subject, in his chapter on "Brewing," to prove the superiority of *Beer*, as a beverage, to *Tea*. He says, in substance, that fifteen bushels of malt will go as far, cost much less, and supply much more nourishment than eighteen pounds of tea. He asserts that "the tea-drinking has done a great deal in bringing the British nation into the state of misery in which it now is," &c. and closes his anathema against the "wretched tea-kettle" and its abominable appurtenances, with the following appeal to an arbitrator, who would, no doubt, give the cause to Mr. C. provided he had legal jurisdiction. "It is impossible," says Mr. Cobbett, "for any one to deny the truth of this statement. Put it to the test with a *lean hog*; give him the fifteen bushels of malt, and he will repay you in ten score of bacon, or thereabouts. But give him the 750 tea messes, or rather begin to give them to him, and give him nothing else, and he is dead with hunger, and bequeaths you his skeleton at the end of about seven days." Mr. Cobbett is a sprightly as well as intelligent writer, and has a fund of humor, by which he gives an interest to subjects, which, treated in an ordinary manner, would be as dry as a Hebrew Grammar. We are therefore, in reading his works, most commonly inclined to laugh *with him*, but in this case we found it impossible not to laugh *at him*. His conclusions have nothing to do with his premises. Because fifteen bushels of malt would furnish more nourishment to a "lean hog" than eighteen pounds of tea it does not follow that tea is to be excluded from a place among those articles which minister to the *comforts and enjoyments*, though they might be struck out of a list of the *necessities* of mankind. Besides, Mr. Cobbett has not fairly submitted his case to his swinish umpire. The case is *Beer vs. Tea*, in *decoction*, and not *Malt vs. the Tea-plant*. If a hog would die in seven days if he had nothing to live on but "*Tea messes*," we believe he could not well be fattened upon *nothing but beer*. The beer does not contain *all* the nourishment which the malt contained, for a great part of the nutritious matter goes with the brewer's grains. Moreover, the beer loses part of its nutrient by fermentation, which converts some of its sugar into alcohol. If Mr. C.'s reasoning were correct, *potatoes whiskey* would be a very *nourishing* kind of liquor, because it is made of potatoes, which contain much nourishment. The value of any substance, as an article of

human diet, is not always in direct proportion to the nutriment which a given quantity of such substance contains. If it were so, a pint of *train oil* would be of more value for food than all the condiments of an Alderman's feast, because a Laplander would support his existence longer on train oil than upon spices, &c. But enough of this. We thought a few words might not be amiss to show that men of strong minds and undoubted talents will sometimes "miss the matter," when zealously engaged in the support of a favorite hypothesis.

We mentioned in a former number of our paper, p. 47, that we could cite the opinions of some eminent scientific characters, among our countrymen, in addition to the testimony of celebrated Europeans, in favor of tea. We now proceed to give the sentiments of Dr. Rush and Dr. Cooper; and we take it Mr. Cobbett himself will acknowledge that we have some weight of authority, if not of argument, on our side of the question.

Dr. Rush says in his lectures, "Coffee and tea excite the understanding in a most agreeable manner. The former was the mental stimulus of Voltaire." The latter was used so constantly for the same purpose by the celebrated Dr. Johnson, that the water in his tea kettle, it is said, was seldom cold. Happily for the interests of science and literature, those two pleasant intusions have been the cordial of studious men, and thereby rescued them from the baneful effects of intoxicating liquors."

Dr. Cooper, in the American edition of Willich's Domestic Cyclopaedia, observes that "much has been said and written on the medicinal properties of tea. *Good tea*, drunk in moderate quantities, with sufficient milk and sugar, invigorates the system, and produces a temporary exhilaration, and clearness of ideas. But when taken too strong and copiously, it is apt to occasion slight tremor and symptoms similar in a degree to those arising from narcotic plants; but as it contains gallic acid and tannin in moderate proportions, I regard it on the whole as a most wholesome, grateful, and economical beverage, affording the safest and pleasantest refreshment after great bodily fatigue, or mental exertion; at the same time tending to support and promote that perspiration, which must otherwise be impeded."

Although we are friendly to *tea*, we are by no means hostile to *beer*, as we hope to show hereafter. But as Mr. Cobbett's authority is considered paramount on subjects of rural economy by many who are interested in the correctness of his statements, we think it highly proper to point out what appears to us to be erroneous in his writings, which, though able, are not infallible.

Mr. Perkins' Steam Engine.—We are happy to have it in our power to give our readers a drawing and description of this wonderful invention. It was well said by a writer in the Encyclopedia Britannica, that the steam engine as it came from the hands of Mr. Watt was the most valuable present that the arts of life have ever received from the philosopher, and the most glorious object, which human ingenuity has yet offered to his contemplation. Every improvement which it has achieved has been the effect of philosophical study. It has now become almost as necessary to the very existence of many important manufactures, as air to animal life. The steam engine presents us a most indelicate drudge, whose strength knows no bounds, and to the utility of whose labors no limits can be assigned. If such was the steam engine, what shall be said of it if it is in the hands of Mr. Perkins, with its powers tenfolded, and its utility increased in as great a proportion? It presents a subject above the reach of reason-

mentation, and a simple description of the machine its most appropriate eulogy. We are glad to perceive that our brethren, on the other side of the Atlantic, disposed to acknowledge the source from whence it derives this "valuable present," and that the Edinburgh Philosophical Journal informs us that "the age of jealousy against America has happily gone by," &c. speaks of the "scientific renown of our great descendants."

From the Central of Wednesday.

BOTANIC GARDEN.

At a meeting of the board of visitors of the *Massachusetts Professorship of Natural History*, September 13, 1832—

The Curator of the Botanic Garden stated, that George Brown, Esq. of Beverly, had presented to the Garden, a very interesting and extensive collection of seeds, and three large boxes of living plants, obtained by him from the royal garden at Rio Janeiro—among which, were the *Artocarpus*, or bread fruit; the *Cinnamon*; the *Campor Tree*, (*Laurus Camphora*); the *Clove*, the black *Ypper*, (*pipier nigrum*); *Criminum*, new yam from Angola; two new varieties of Orange from China; a seedless variety of the Orange, large and well flavored; the *Time Tree*; several species of *Epidendrum*, and *Tillandsia*; together with several bulbs, not yet known. The whole of them very desirable, and most of them not before in the garden. Mr. Brown also offered to obtain for the garden, any Brazilian plants which were requested.

Vote, That the thanks of this board be given George Brown, Esq. of Beverly, for his valuable present of a fine collection of plants, collected and purchased by him at Rio Janeiro, which plants are very rare and arrived in fine order at the Botanic Garden; Cambridge; and that the Corresponding Secretary be pleased to express to Mr. Brown their further thanks for his offer to add to his past benefits, such plants as he may hereafter have an opportunity of procuring.

Copy from the Record.

BENJAMIN GUILD, Secretary.

From the N. Y. National Advocate.

Horticultural Society.—It will be seen by the following extract from minutes of the proceedings at a meeting of the New-York Horticultural Society, that Mr. Douglas, the eminent botanist, of whom we spoke a few days since as having been sent to this country by the London Horticultural Society, has returned from Philadelphia, and is prepared to commence his examinations and collections in this vicinity, aided by the counsel and assistance of a committee of the New York Society, selected from among its most scientific and efficient members.

At the monthly meeting of the New York Horticultural Society, held at the Broadway-house on Tuesday evening, Aug. 26th, letters and other communication from the London Horticultural Society were received with offers "to establish a reciprocal communication on the science to which both societies are devoted."

The same being taken into consideration, on motion of Dr. Hosack, Resolved, That a committee of five be appointed to confer with Mr. Douglas, the representative of the Horticultural Society of London, now in this city, and afford him every aid in effecting the objects of his mission. Whereupon, the President, Vice-President, Secretary, Dr. Hosack and Thomas Hogg, were appointed to compose said committee.

A committee of three was appointed to inspect some Spanish tobacco raised from Havana seed by Dr. Barton.

Fine melons were exhibited by Mr. Wilson and Mr. Codie; a number of the peaches and grapes by Mr. Shaw; two very large peppers of a new sort from Cuba, were presented by Mr. White, one of which measured seven inches round; a very large leaf of tobacco, so called from seed obtained from the South Sea, was presented; also specimens of *Coclea Scandens*, a beautiful running plant from Mexico, by Mr. Codie.

Extract from the minutes.

MICHAEL FLOY, Secretary.

William Almy, Esq. has presented the editor of the *Residence Journal* with two apples, not fully grown, one of which is 12, the other 13 inches in girth.

FOREIGN.

Spain.—We have, within this week past, received from Spain of all kinds and qualities, some re-calculated to invigorate hope, and others to cre-spondence in the friends to freedom and to Spain. balance, however, is at present greatly against ish independence. The Constitutionalists fight-ly, but the mass of the population are not hearty cates of their own cause. They seem to court chains, and have a kind of affection for thie-les, which has been generated by habits of sub-on to despotic authority.

ie last accounts from the seat of French and Span-olities were received by the ships Topaz and-ica, which arrived at this port on the 15th inst. ce it appears that the Duke d'Angoulême had lalrid, and was on his way to Seville. The sieg-rouna is continued. Gen. Quiroga, at the last, was in London, about to embark for Cadiz. Bal-os has been defeated by Molitor. Gen. Wilson at Vigo, and had opened a correspondence with Morillo, which had for its object a termination of ties, but terminated in nothing. The siege of-ia was pressed with vigor, and the place as vigor-defended. Gen. Morillo was overrunning Gal-ithout meeting much opposition. A new corp-sch soldiers, under Gen. Lauriston, had enter-ed, with a large train of battering artillery, and had ended the siege of St. Sebastian.

ia, Morillo, Count of Carthagena, by a decree of-ish Cortes, has been declared a traitor, and ed of his rank, title and dignities.

Spain Successful.—Papers received since the- was written, give a more favorable aspect to-ish affairs. The state that in the battle between-terbs and Molitor both sides claimed the victo-rie battle had been terrible, both parties kept the- and the action would be renewed under cir-umstances highly unfavorable to the French. Ballo- however, had taken the French artillery. Moril-o neither recognize the Cortes nor the regency; his- have denounced him and he has fled. Quiroga- assumed the command of the troops, who are in- spirits, 3000 strong. The garrisons of St. Sebas- and Pampeluna have made successful sorties, and- ed the French to abandon their camps. Provi-ers cheap in Cadiz, the prices falling, and there- prospect of the speedy surrender of that place. Galonia "there is no end to fighting, and the- rds always successful."

DOMESTIC.

Harford Cattle Show.—The Cattle Show and Fair- Harford County Agricultural Society will take- n that city on the 8th of October.

Orchard Trees.—Mr. Denniston, of Albany, has cul-ti-planted trees in his fine gardens near that city, to- perfection. He has twenty-five different kinds- produce such an abundance beyond the supply- family and friends, as to enable him to dispose- worth in the public market in one season.

Fruit.—A New York paper says, "We under-stand that Mr. Shaw presented to the Horticultur- at, at their last meeting, some elegant specimens- among which were two new species of the- the Marie Antoinette, imported from France. Unique which originated in Mr. Shaw's ground, ed the pleasure of viewing the fruit; it is of sin- eauty, and exquisite flavor, and is a desirable- tion to our present stock."

Molasses.—We are informed that molasses of- quality has been made the present season, in- Carolina, from the juice of water melons boiled

Sport.—On Friday last, as Mr. James Jackson, (L. L.) who had been out with a party of gen- hunting Deer, was returning home, he fell in- den of Rattle Snakes, and actually shot and- fourteen, which he exhibited in the evening to- ther sportsmen. How many got away. (says- skson in his letter to us) I cannot say, as it was- icket of wood where there was a great deal of- rush."—N. Y. Evening Post.

Extract of a letter from an officer on board the U. S. frigate Congress, dated Gibraltar, July 27, 1823.—We have been off Cadiz for the purpose of landing Mr. Nelson, our Minister to the court of Spain, but we were not permitted to pass the French squadron which is blockading the place. The King is closely put up there, by land and sea. The French are overrunning all Spain, and meet with no manly resistance from the garrisons. Indeed, the latter seem rather inclined to sell their country for gold, than to defend it with arms.

Thieves.—This section of the state has recently been visited by a horde of wretches, who have plundered property to a considerable amount. Four or five horses, fifteen hundred dollars in cash, and several articles of less value, have been stolen in this and the adjoining towns within a few days. It behoves every inhabitant to guard against similar depredations, and to be on the alert to detect these villains. The societies in Milton, Ballston, Galway and Greenfield, for the detection of horse thieves, have proved very beneficial. Since their formation, scarcely a horse thief, who has dared to infest those towns, has escaped; and we are glad to perceive that a similar society is about being formed in this town.—*Saratoga Sentinel.*

The Belfast (Maine) paper of the 10th inst. says, The weather has been for a long time past and continues to be extremely dry. The woods all around us are on fire, and this village literally enveloped in smoke. Several alarms have been given, when buildings were supposed to be in danger, and the engine-men and other inhabitants turned out with promptness and alacrity. We have heard of no buildings being burnt in this town or its immediate vicinity.

Fire in Maine.—The fire in and near Wiscasset was very distressing. One aged female was burnt to death in attempting to escape from the flames. Another saved herself by descending a well, into which she had previously thrown a chest and bed. "It was indeed," says one of the papers, "an appeal to the most obdurate heart to see the frantic mother with her affrighted children, running to and fro, through a burning forest, without a prospect of retreat or a hope of refuge. Such was this fire, which in the short space of two hours, levelled with the ground, buildings, trees and fences to the extent of seven miles in length and three in breadth. It might well be termed a flaming whirlwind, spreading dismay and despair, and leaving nothing but the last consolation of the wretched, the safety of their lives."

An end of blue cloth, 11 1-2 yards, being part of a piece manufactured by Mr. William Hirst, of Yorkshire, Eng. was sold yesterday, at auction, by Messrs. Boggs, Thompson, & Co. for \$17 75 per yard. It is understood that the Emperor of Russia, the King of England, and the President of the U. States have each had a coat from the same piece.—N. Y. paper.

Pyroligneous acid.—The Statesman informs us, that the body of Mr. Senator Boardman, who died in Ohio, has been brought from that state in a perfect and unaltered condition, by being preserved in pyroligneous acid, a chemical preparation now in general use for preserving animal substance. We have for some time been of opinion, that pyroligneous acid far exceeds the Egyptian gums and spices used by the ancients for embalming the dead; and bodies thus preserved will last for ages unaltered in their features, and but slightly in complexion.—N. Y. Advocate.

Industry is the fountain of Independence.—We are informed by a gentleman of veracity, that there is a boy living in Newton township, in this county, who, during the last winter, spun from tow, and with five needles knit himself a pair of pantaloons with suspenders and stockings complete. The whole was done in nights by firelight, for he is obliged (though but thirteen years of age) to work in the day time for the support of his aged parents. His name is William Pickle. He has it in contemplation to construct another pair out of wool. The independence of his mind, for one of his age, is truly astonishing. On being offered a present of sufficient wool to make his intended garment, he refused, saying he could earn it himself.

Zanesville (Ohio) Messenger.

PATENT CAST STEEL HOES, &c.

RECEIVED by the Emerald from Liverpool, and for sale at the AGRICULTURAL ESTABLISHMENT, No. 20, Merchants' Row, a further supply of English Cast Steel Hoes, of a superior quality.

On hand, a large supply of
Steel spring-tempered Potatoe Hoes,
Best warranted Bush Scythes,
Patent Scythes Smiths fitted to the same,
A few very superior ivory handled Bulldog Knives,
Steel and Iron Bull Rings,
Copper Funigators,

with a large and general assortment of
AGRICULTURAL & GARDENING IMPLEMENTS.
September 13.

PRICES OF COUNTRY PRODUCE, &c.

[Revised and corrected every Friday.]

FEMALE FELICITY.

What happiness the rural maid attends,
In cheerful labor while each day she spends!
She gratefully receives what Heaven has sent,
And rich in competence enjoys content;
(Such happiness, and such unblemish'd fame
Ne'er glad the bosom of the courtly dame.)
She never feels the spleen's imagin'd pains,
No melancholy stagnates in her veins;
She never wastes her life in thoughtless ease,
Nor on the velvet couch invites disease.
Her home-spun dress adorns her person more
Than all the gew gaws grandeur ever wore.
In reputation (which is all her boast)
She stands superior to each reigning toast,
For malice never meddles with her name,
Nor envy dares her purity defame.
No midnight masquerade her beauty wears,
No paint her waning loveliness repairs;
No home-bred jars her quiet state control,
No watchful jealousy torments her soul.
If love's soft passion in her bosom reign,
An equal passion thrills her happy swain:—
Soon Hymen joins assenting hearts and hands,
The parson twines and sanctifies the bands.
At length with joy she sees her little race
Hang on her bosom, and her cottage grace;
The dainty ball their busy fingers cull,
Or from the spindle draw the length'ning wool;
Thus flow her hours with constant peace of mind,
Till age the latest thread of life unwind.

From the Providence Journal.

We have in fresh recollection, an incident, which led to the separation of man and wife, which in the original was the most trifling; but in the sequel was disastrous and distressing. A gentleman received one morning, when at the breakfast table, a cup of coffee from the hand of his wife, which contained the oil of a small piece of butter which had accidentally fallen into the cup. Louisa, said the husband good humoredly, I'll thank you to give me a cup of coffee that is pure and unadulterated. Henry, replied the wife, do you think it is poisoned? No, certainly not, but I should prefer having another cup. Indeed you shall, replied Louisa, but permit me to drink that which you complain of. No, madam, you shall not, replied the husband sternly, and instantly threw the contents of the cup into the bosom of Louisa. She rose hastily from the table, looked wistfully towards Henry, and wildly gazed on all around her. With lingering steps she moved from the apartment, and for the last time looked a farewell to Henry.

An uninterrupted silence ensued, but when the consternation of the persons present subsided, the distracted husband, in a paroxysm of despair, rushed into the street, and followed the footsteps of crazed Louisa. In vain he sought her in every nook and corner of the city, for she was not to be found, and the frantic husband returned hopeless and hapless to his desolated mansion, where he indulged in excessive sorrow and despair. Scarce two hours had elapsed before Mrs. A. was returned to her husband, not glowing in youth and beauty, but a lifeless corpse. The treatment she received from him she loved, crazed her, and in the moment of distraction she committed suicide. Mr. A. survived the shock a few months, when he expired, and in his last moments lisped the name of Louisa, and prayed for her forgiveness.

From the Old Colony Memorial.

Various as the inclinations of men, are the occupations of life. Labor for support, was in the beginning, the appointment of Heaven. It has ever been, as it were, a condition of human existence. He who is *too good*, or rather *too indolent*, to make exertion, is too good, or rather too indolent, to live.

But in no employment, can so much profit be combined with so much pleasure, as in that of Agriculture. Although the farmer is not distinguished with the same honors that a grateful country bestows on her warriors, be it remembered, the wreath of the victor, the price of "garments rolled in blood" is to be obtained only at the risk of life and fortune. Although he does not share with the seaman, in the charms of novelty, the delight of gazing at the wonders of distant cities, yet winds and waves and lawless men perhaps must be encountered, before these charms of novelty, these distant cities can be brought to view. The cup of the farmer is not thus mixed with doubt and uncertainty. Raised not above the common level of mankind, he is equally free from the wants that creep around the cottages of the poor, and the plagues that haunt the door of the wealthy. Not depending upon other men for his food and clothing, he possesses and can use them at his will. To labor in the season for laboring, is no more than he expects; and when the frosts and snows of winter have bound him to his cottage, he enjoys the fruit of his labors. In such enjoyment, there is more satisfaction than the splendid retinues and luxurious feasts of Emperors can afford.

"Thus in some deep retirement, would I pass
The winter glooms, with friends of pliant soul,
Or blithe, or solemn, as the theme inspired."

"Two pence for my cresses," cried a little boy in the streets of Philadelphia one day—he is now an eminent merchant and worth millions of pence—"La! pa, how mean it looks to see that little boy crying cresses for two pence," said a little gentleman whom he passed one day—that person died a poor creature in gaol. Learn this lesson. Two pence is but the beginning of shillings—shillings of fortune—fortune of ease and luxury. Look well to your two pences and fear not. But neglect them and they will neglect you—they come not like the physician in the hour of adversity, but when the sun is up and the day of health lasts.

Romantic Lover.—A romantic story is related of an Englishman, who sought the hand of a very charming lady, with whom he was passionately in love, but who constantly refused him. As he had reason to believe she loved him, he entreated to know the reason why she refused her consent to their union. The lady, subdued by his constancy, told him that her only motive for refusing him was, that having by an accident lost a leg, it had been replaced by a wooden one; and she feared that sooner or later this circumstance would chill his affection for her. This she declared to be her only motive. The lover protested that this would never make him change his love; but she persisted in refusing to marry him. Fired with love, and determined that nothing should obstruct his design, he, under the pretext of going a distant voyage,

left the lady and hastened to Paris, where he had one of his own legs amputated. When he had recovered, he returned to London, went to the lady, and told her that there was now no obstacle to their union, for that he was equal to her in every respect. The lady, conquered by such a proof of affection, at last consented to marry him.—*Athenum.*

Double-tongued Lady.—The Brighton (English) paper mentions, that there is at present residing in Brighton, a lady of great beauty and accomplishments, possessed of a quality which puts out of all distance the fame of the celebrated Mr. Doublelungs. This extraordinary singular faculty arises from a peculiar formation of the tongue, which is separated to the root, a longitudinal direction, and actually forms *double tongue*. Not the slightest inconvenience is felt from the exuberant gift of nature. With this desirable and admirable addition to the organ of domestic comfort, this lady is enabled to afford entertainment to her friends, beyond the power of any ventriloquist, or indeed conception. From the personal charms she possesses as well as a highly endowed mind, she has many suitors, some of whom have retired for paying homage, owing to the effects of the *clapper* hung in this enchanted *belle*. She possesses two voices: one exceedingly clear, sweet, and harmonious, allowing her to sing with great effect; the other so exquisite, thrilling, that it must have been bestowed on her for no other purpose than to lisp the smallest voice of love. With this voice she imitates exactly the notes of many birds, pipit like a bulfinch, singing as a canary. What remarkable, her mother was deaf and dumb.

Suit at law.—Two suitors at court being reconciled to each other after a very tedious and expensive suit, applied to an artist to paint a vice in commemoration of their returning at peace and peace. The artist accordingly painted it in his shirt and the other stark naked.

I will admit that it is impossible for any man not to have some enemies. But this truth from long experience, I assert that he who has the most friends, and the fewest enemies, is the strongest; will rise the highest with the least envy; and fall, if he does fall, the gentlest, the most pitied. This is surely an object worth pursuing. I will add one observation more and then conclude. There is no one creature so obscure, so low, or so poor, who may not, the strange and unaccountable changes and vicissitudes of human affairs, somehow or other, become a useful friend, or a troublesome enemy to the greatest and the richest.—*Chesterfield.*

There are people, who, like new songs, are in vogue only for a time.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrearages are paid. Agents who procure seven subscribers, and become responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

GATHERING AND SECURING POTATOES.

It must acknowledge that the topic of our next discourse is somewhat thread-bare, and likely to be very fertile in entertaining matter. But, though we may state what many of our readers knew before, our observations may be new to some; and will, we hope, be thought interesting, because it may be for some people an interest to attend to them.

With regard to the time in which potatoes should be dug, we find some difference of opinion amongst practical farmers with whom we have conversed. It is acknowledged by all that potatoes should not be taken from the ground till they are fully ripe. This may be known by the appearance of the tops, which will begin to wither as soon as the roots have arrived at maturity.

After that period, we are told by some, that it is important that the potatoes should be gathered and housed as soon as possible; and others say that they will keep as well in their native beds till frost comes, in any other situation. Some say that the roots will actually increase in size as well as in quality, after the tops begin to decay; and therefore digging potatoes ought to be the last work, which the farmer performs in the autumn before the ground freezes. And a writer in the American Farmer, vol. i, p. 154, says potatoes should be dug as soon as ripe up to a second growth. But we do not think it is dangerous in our climate of potatoes growing in one season. We cannot say, however, which of the opinions relative to early or late digging is most correct, but till better informed should feel disposed to gather potatoes as soon as convenient after the tops are decayed, either by ripeness or by frost. At any rate, we should not put off the digging of them till very late in autumn lest cold weather should destroy or lock them in the ground till

the most expeditious way of gathering a potato is, first to run furrows on each side of the rows, and then a deep one in the middle, turning up most of the roots to the surface for the purpose of picking up by hand. In this, however, we should apprehend some care should not advise it except when power is very plenty and labor scarce. A fork with four prongs, with the addition of a handle may be called a fulcrum, fastened by a rope to the back part of the handle, and used for raising potatoes without the aid of a plough. This is recommended by the Agricultural Assistant, but we believe that a hoe with four prongs, (such as are sold at the Agricultural House of Mr. J. R. Newell, No. 20, Cornhill's Row, Boston) would be a still better instrument for the purpose of gathering this

old-fashioned mode of harvesting potatoes which is now very justly rejected by all enlightened husbandmen) was to dry them in a shed as much as you would grass, intended for cattle. This was formerly for and ought we

know to the contrary, is still the practice in Great Britain. Rees' Cyclopaedia, (Art. Potatoes) says "As soon as potatoes are gathered they should be allowed to remain *some days to dry, before they are stored.*" This is exactly wrong; and in our climate, an exposure of two or three days to a cloudless sun in September or October, would cause potatoes to turn green, strong, and become in some degree, poisonous. It is now said by practical farmers that the less the roots are exposed either to sun or air after being taken from the ground the better, and that it is well to permit some part of the soil in which they grow to adhere to and be mixed with them, when they are deposited in their winter quarters. It is recommended, however, not to dig and house potatoes immediately after a soaking rain, but to let them remain a few days in the hills, to get rid of their superfluous moisture, which, according to some rural philosophers, will in due time, be expelled by the principle of vegetation, or vital energies of the root, unless the ground is very wet.

In some parts of Great Britain the farmers are very careful to sort and separate their potatoes in the field, when they gather them, putting those which are small, diseased or cut with the hoe by themselves, to be used in autumn, or the fore part of the winter for the feeding of stock, &c. This is, no doubt, a very correct mode of procedure, and those who are not too much in a hurry to do their work well, will find an advantage in adopting it. Others assort their potatoes when they store them, by letting them run down an inclined plane of net work made of strong wire, with meshes which will permit the small potatoes only to pass through them.

There are various modes of securing potatoes for winter and spring use. Almost any method will answer by which you can keep them from water and frost. We will however describe or advert to some directions given by different writers relating to this subject, which may perhaps be of use to some, though they suggest nothing new to some others of our readers. Dr. Deane says "there is no difficulty in keeping potatoes through the winter in a cellar that is free from frost. Caves, dug in a dry soil, preserve them very well. They should be covered with two feet of earth over them. If they are in danger of frost in a cool cellar, they should be covered with a little salt hay [probably straw or fresh hay will answer.] In cellars they are more forward to sprout in the spring than in caves." In Lancashire and some parts of Scotland, it is a common practice to dig pits in the potatoe field, where the soil is light and dry, and putting in potatoes to the depth of three or four feet to lay a litter of dry straw over them, and then cover them up with earth so deep that no frosts can affect them. Mr. McMahon gives the following directions for preserving turnips, carrots, parsnips, &c. which we presume would answer as well for potatoes as for either of those roots. "On the surface of a very dry spot of ground, in a well sheltered situation, lay a stratum of sand two inches thick, and on this a layer of roots, covering them with a layer of sand, and so continue layer

about of sand and roots till all are laid in, giving the whole, on every side a roof like slope; then cover this heap or ridge all over with about two inches of sand, over which lay a good coat of drawn straw up and down as if thatching a house, in order to carry off wet and prevent its entering to the roots; then dig a wide trench round the heap, and cover the straw with the earth so dug up, to a depth sufficient to preserve the roots effectually from the frost. An opening may be made on the south side of this heap, and completely covered with bundles of straw so as to have access to the roots at all times, when wanted either for sale or use.

"Some people lay straw, or hay, between the layers of roots, and immediately on the top of them; this I do not approve of, as the straw or hay will become damp and mouldy, and very often occasion the roots to rot, while the sand would preserve them sweet and sound." We think that this method of preserving such roots as would probably be wanted in the winter would be found preferable to putting them in caves, or pits, which it might be difficult to open and close after severe frost has commenced. They might, no doubt, be preserved in the manner pointed out by Jesse Buel, Esq. (in the first volume of this paper, page 106,) for securing ruta lagas; but as they would be more liable to be injured by frost than that root, they would of course require a thicker coat of earth or other material for a covering.* Care should be taken not to lay them in too large masses lest they heat and spoil. If you have great quantities to preserve you may either make a proportionate number of pits or heaps, or place them in a trench or row, which may be longer or shorter as the case may require. They should have a light covering when first buried as they will sweat, and be apt to rot if placed in too warm a situation; and as winter approaches more earth may be placed over them, till they

*On reflection we believe it will not be amiss to give, in this place, Mr. Buel's directions on this subject, in order to accommodate such of our readers as may not be in possession of our first volume. "To preserve the roots dig about one foot deep on the side of a hill, leaving the bottom inclining, and sufficiently broad each way to be able to pile in the space, in the form of a cone [or sugar loaf] 100 bushels. Place the roots in it, and bring the top to a point as far as practicable. Cover with straw and then dirt. They will bear considerable frost without injury; [potatoes are more liable to injury from frost.] Take care to dig a trench round the mound to turn off the water."

A writer with the signature "A Farmer," whose communication was published in our paper, vol. i, p. 354, gives the following mode of securing potatoes, which we believe very judicious, and republish for the reasons above mentioned. "When the potatoes are ripe in the fall, that is when the vines are dead, I dig them and put them into a pit, dug on a knoll with a trench two feet deep, leading from the pit out, in which I place a common pump log, with the end to the edge of the hole. After placing boards over the hole, cover the whole with a thickness of earth sufficient to prevent the frost from reaching them. In this way any quantity can be put together without any danger of their heating. Care should be taken to prevent the mice from getting to the hole thro' the log, by nailing a piece of tin with holes punched in it at the outer end."

are perfectly secure from the severest frost.—We have mentioned before that it was once thought necessary to expose potatoes to several days of sunshine before they were housed; an error which is now pretty generally exploded. But there is another practice which we believe is not correct, although it is, perhaps, often adhered to. Potatoes designed for the table are often packed away in sand, and may be very well preserved in that manner. It was formerly thought necessary that the sand in which they were placed should be *perfectly dry*. But we have been told by good practical farmers not only that potatoes should not be dried in the sun, when dug, but that they are best preserved in *moist* sand. Some say it is as well to dig, gather and house potatoes in rainy as in fair weather, much better to choose a cloudy, cool and damp than a clear, dry and warm day for that purpose, and even "wet sand" is most eligible to preserve them in. The Farmers' Assistant assures us that "A planter of North Carolina sent some potatoes to the West Indies for market; a part of which were dried in the sun, in the usual way, and a part were laid away in *moist or wet sand* as fast as they were dug; and when exposed for sale he obtained *three times the amount*, per bushel, for those laid in sand, than he got for the others. We mention this circumstance, in order to observe that such potatoes as are designed for the table should be laid away in *wet sand* as fast as they are taken from the earth." We perceive nothing unreasonable, or unphilosophical in the supposition that potatoes, as well as other roots, may require moisture to preserve their life, their vital, or vegetable principle. There is no danger of their growing, or sprouting, unless to moisture be added *warmth and air*. Seeds of plants, we are told by good authority, are best preserved "by causing them to be packed either in husks, pods, &c. in absorbent paper with raisins, or brown *moist sugar*." And if so, is it not probable that *moist sand* may answer for preserving roots, fruits, &c? The *degree* of moisture proper for sand intended for such uses, we can say nothing about, except we have preserved parsnips and carrots through the winter and spring till June, by packing them in sand taken from a bank, and used immediately, without any attention to drying it. The sand was, we believe, a little *damp* but not very *wet*, and that is the state in which we should (as at present informally) recommend using it. It might be well, however, to try a few roots packed in sand fully or nearly saturated with water, and note the result of the experiment for the benefit of your future management of this important branch of household economy. Perhaps the *secret potatoe* which many have attempted in vain to preserve in *dry sand*, might be well kept in *moist sand*; and if so the most serious obstacle to the cultivation of that important root in the northern part of the union will be removed.

FOR THE NEW ENGLAND FARMER.

CIDER.

Good cider is probably as pleasant and wholesome a drink as any that is or can be made of. Yet a very large proportion of the cider that is made is both unpalatable and unfit to be used. We not unfrequently hear people complaining that their cider is bad, and wondering what the cause of it is. Some people might be

informed that it is neither mysterious nor unaccountable why they do not have good cider.—If there be proper care and attention in making and managing cider, there is very little doubt but that it will be pleasant and good; while on the other hand, if suitable care and attention be wanting, it is as certain to be unpleasant and bad. There are a few things, the observance of which are necessary in order to have good cider. It does not depend altogether, nor principally, upon the kind of apples, for there are but few sorts but what will make good cider if rightly managed.

Apples should be thoroughly ripened, and gathered when perfectly dry and put into the cider house, where they should be kept until sufficiently mellow to be ground, which should be done before they become rotten and musty. Cider should always be made in cool weather, the wind blowing from the W. or N. W. If it be made when the wind blows from the South it is almost certain that it will be hard and unpleasant. Cider should not be pressed out of the pomace sooner than ten or twelve hours after the apples are ground, as the flavor will be better by thus remaining. After it is pressed out it should be strained through sand, which will take out all the sediment, and thereby prevent its working or fermenting too much. This operation is simple and easy, and attended with very little labor or expense. Sand of a coarse kind should be procured from a river or pond and put into a cistern suitable for the purpose, first placing a layer of straw at the bottom to prevent its washing through. Having thus prepared for straining, put in water sufficient to wet the sand and thoroughly raise out all the dust or fine dirt, which will be done as soon as the water runs clear. The cider should now be put into the cistern as it runs from the press, and as fast as it runs through the sand put into suitable casks and placed in a tight cool cellar, and after the fermentation is over be bunged tight, and thus remain until wanted for use.

Neatness and cleanliness are essential and indispensably necessary in order to have good cider. The cider mill, and every thing connected with it, should at all times be kept perfectly sweet. Pomace should not be permitted to remain on the press after the cider has done running from it, as it will immediately become sour, should the weather be warm. Straw and litter of every kind should be kept entirely away, except what is necessary to be used.—The manure of the horse should be cleaned away as soon as it is dropped. In fact, the cider house, the mill, and every thing appertaining thereto, should be kept as free from dirt and filth of every kind even as the kitchen or parlor.

I know of one distinguished farmer who during the winter shelters his sheep and calves in his cider house. Another within my knowledge makes use of it as a slaughter house. He butchers his hogs therein, scalds them in his cider tub, and dresses them on the press. I have been at some cider mills where the straw and pomace, the horse droppings and other filth, rendered it almost impossible to stir about.

As long as habits of this description are persisted in, so long we must expect to hear people complaining about their cider.

A FARMER.

Worcester, Sept. 1833.

To the Editor of the New England Farmer.

DEAR SIR—If the following Notes from Professor Day's Lectures, describing the best mode of constructing chimneys, can fill up a corner of your valuable paper with advantage, you are at liberty to make use of them.

CHIMNIES.

A common opinion concerning the ascent of smoke is, that it is *drawn up*; but the truth the smoke is *pressed up* by the cold air which coming to the fire place from the room. A warm air rises upon the principle of specific gravity and carries the smoke up with it. Smoke is *not lighter* than air of the same temperature but it rises principally because it is in the current of heated air. Dr. Franklin by a very simple experiment with a tobacco pipe has demonstrated this fact to every one's satisfaction. The great art then of making the chimney carry smoke consists in producing this current; i. e. removing as much as possible every obstruction to its passage. The funnel should be made *smooth* as possible. It should be plastered, kept clear as may be of soot and should be large enough to admit the whole of the hearth air.

1. The funnel should be made as long as convenient. For the force of the current is proportioned to the difference between the weight of the air in the chimney and the weight of a column of the same height without it. The reason that rooms in the upper floors are more liable to smoke than those in the lower unless they be made proportionably small. An imperfect draught may often be remedied merely by raising the top of the chimney. A very common defect in the chimneys in this country is that the funnels are much too large. It requires a good fire to heat so considerable a body of air. To make the funnel bend is no advantage to the draught, but rather impedes it. But it is of use to prevent the fall of ice and snow, and obstruct the progress of sudden gusts of wind. The turn should be gradual.

2. The fire place should be constructed in such a manner, that *all the air* which passes to the funnel should be heated as it passes the fire. Count Rumford found only one out of five hundred where the smoking of a chimney was owing to any other cause than the improper dimension of the throat and fire place. The throat need not be more than four inches in depth in almost all cases. The mantle piece is often too high. This construction has the advantage of throwing more heat into the room and if there is no danger of smoke the higher the mantle piece, the better. The fire place must not be made very deep. Almost all smoking chimneys may probably be remedied by raising the mantle piece. The fire place should never be wider than is sufficient to receive the wood. But supposing that the chimney is constructed in the best manner possible, it is certain that it will carry the smoke well. Nothing is further necessary—the constant supply of fresh air from the room. Rooms in a house are apt to be filled with smoke because they are too tight. Move the door back a fourth until you find the least opening which clears the room of smoke. Calculate the number of square inches in this;—and an opening in any part of the room may be made of the same extent.

From Cox on Fruit Trees.

THE PLANTING AND CULTIVATION OF ORCHARDS.

The first thing to be determined upon in the planting of an orchard, is the proper distance between the trees: if a mere fruit plantation be the object, the distance may be small—the cultivation of grain and grass be in view, the space between the trees must be wider: at thirty feet, an acre will contain forty-eight trees; at fifty-five feet, thirty-five trees; at forty feet, fifty-seven trees; and at fifty feet, about eighty to the acre—these are the usual distances. In my own plantations, I have adopted the various distances according to the depth and character of the soil; about two thirds of the ground, producing about one hundred acres, are planted 50 feet; on the remaining fifty acres, I have tried 20, 35, and 10 feet; and as far as could be conveniently done, I have planted the spaces of smallest growth on the lightest soil; in every circumstance into consideration, it is probably be found, that forty feet is the most eligible distance for a farm orchard. It admits sufficient sun and air, in our dry and cold climate; and until the trees shall be fully grown, will allow of a profitable application of ground to the cultivation of grain and grass.

Such trouble will be saved, and much accuracy in planting will be insured, by marking the positions of trees by stakes previous to digging the holes. In shallow soils, I would recommend digging the holes of the depth of two spits of soil, scattering the lower spit at some distance; supplying its place by an equal quantity of neighboring surface earth—the depth of the hole must depend on that of the sub-soil. In the most eligible mode, which I have practised with success in a large portion of my orchards, in the lighter soils, is to supply the place of the bottom of poor earth, by one or two loads of low mud, ditch banks, or good surface soil, round each tree after planting; ploughing the ground for a fallow crop the next spring, when the mud has become completely pulverized by the frost; the size of the hole should be sufficiently large to admit a spade handle, laid horizontally in the bottom; affording the space for the expansion of the roots in the rich earth. Well digested compost is used around newly planted trees, in stiff or cold soils—both lime, and fresh stable manure, I have found prejudicial in the dry and hot weather of summer; the latter substance is also frequently a cover for moles and field mice, which are extremely injurious in winter, to trees of six or eight years old in light soils. I have derived great benefit from the application of evenings of manure on the surface, and mixing it equally by cultivation of the soil, as the best remedy against drought in summer, and vermin in the winter.

The proper season for planting, will be found to depend on a variety of circumstances—in cold soils, the winter settles the earth round the roots, and best secures them against the rigors of the following season—it is a time of repose to the farmer, and affords an early season of trees from the nursery. In stiff or cold soils, I should give a preference to spring planting, other circumstances being equal—I have planted at both seasons, and have generally found that care and attention ensured a corres-

pondent success in the growth of my trees. In whatever season an orchard may be planted, too much attention cannot be given to extend the roots in every direction; to cut off all wounded parts, and more especially, not to plant too deep: this I believe is the common error of inexperienced planters: as a general rule, I would recommend that the tree be placed in the orchard with about three inches of earth over the upper tier of roots, which will make it about two inches deeper than it stood in the nursery; that the tree, after being partially covered, should be well shaken, to admit the finer particles of the earth among the fibrous roots, and that it be well settled, by treading the earth around it—with these precautions, I have never found the necessity of stakes. The tops of young trees should never be shortened, lest it should produce a growth of suckers: I would recommend in preference, that they be thinned, if found too heavy: if the trees have been long out of the ground and the roots have become shrivelled at the time of planting, the labor of pouring a pail full of water round each tree, will be amply repaid in the success it will ensure in their growth.

The looser the ground is kept for the first, and for several succeeding years, the more certain and more vigorous will be the growth of the orchard—in the luxuriance and color of the foliage of contiguous plantations, I have found every stage of cultivation strongly marked: those orchards which have been two years under cultivation, exhibit a striking superiority over those which have been but one year under the plough; while these, in their turn, surpass the fields in clover or in grain, both in the quantity and size of the fruit: when clover is sown in young orchards, I have been in the habit of digging the earth for about three feet, at the root of each tree: a man will dig round one hundred trees in a day; the trifling loss of grass and labor, will be fully remunerated by the improved vigor of the tree. When the ground can be spared from cropping, four or five furrows on each side of a row, will be found a most eligible mode of promoting the growth of a young orchard.

All fallow crops are most favorable to the growth of orchards, at every early stage of their cultivation—Indian corn, potatoes and vines, are preferable to oats or barley; and these again are more favorable than winter grain: Buck-wheat is among the most beneficial crops for the promotion of the autumnal growth of trees—Clover is by many farmers believed to be injurious to young trees; its tendency to check the growth of trees will be found, I believe, to be in proportion to the air and moisture which its greater or less vigorous growth may keep from the roots; light and heat, appear as necessary to the roots as to the branches of trees—clover, while it occupies the ground, must prevent cultivation; so far I apprehend it will be found pernicious, but probably not in a greater degree than any other luxuriant and deeply rooted species of grass, absorbing the moisture, and exhausting the strength of the soil, which covers the roots of small trees. In the arrangement of an orchard, both convenience and beauty will result from planting each kind in distinct contiguous rows. Some cultivators pay particular attention to continue in the orchard the aspect the tree maintained in the

nursery: I have sometimes adopted the practice without much confidence in its efficacy; nor can I think it probable, that trees growing in close rows, not much exposed, in the nursery, can by any habit so limited in its duration, be affected by any permanent contraction or rigidity of the bark, or sap vessels, which are the only effects I have ever heard ascribed to the influence of aspect, on the stems of young trees.

The prevalent winds of our climate, are from the north west: in light soils, their violence will sometimes give an inclination to newly planted trees to the south-east: this may easily be remedied by setting up the trees while young; and when they have attained a large growth, it may be overcome in a great degree, by cutting off the leaning branches, and by freely pruning the leeward side of the tree.

Moss is a plant produced by poverty and neglect; it is very prejudicial to trees, and should be carefully removed: this can be readily done, by rubbing the trees in damp weather with a bone, or the back of a knife; good cultivation will generally prevent the growth of moss—white-washing the stem, not only cleanses the tree of moss, but destroys many kinds of lice very injurious to fruit trees; it is followed by a cleanliness in the bark after it has been dissolved by rain, and promotes the health and vigor of the tree whenever applied.

To preserve Grapes on the vines till winter.—About September, when grapes are nearly ripe, procure some bags made either of crape, muslin or white paper.

Select some of the best bunches, and with a pair of sharp narrow-pointed scissors, cut off all small unripe, rotten, mouldy, or imperfect grapes, especially those eaten by flies or wasps.

Enclose each bunch in a bag, and tie the bag fast with a string, so that no insect can get into it. In the middle of a fine day in October, gather them, with a piece of the sheet to them, and hang them up in a dry warm room.

Dip the end of the shoots in melted rosin or sealing-wax. Examine them frequently, lest they should get mouldy or rotten.

To preserve Apples.—Dry a glazed jar perfectly well, put a few pebbles in the bottom; fill the jar with apples, and cover it with a bit of wood made to fit exactly; and over that, put a little fresh marlar. The pebbles attract the damp of the apples. The mortar draws the air from the jar, and leaves the apples free from its pressure, which, together with the principle of putrefaction which the air contains, are the causes of decay. Apples, kept thus, have been found quite sound, fair, and juicy, in July.

Birds Eye Maple.—Perhaps it is not generally known to our farmers in this section of our country, that this beautiful wood is becoming a very valuable article of Cabinet furniture. The superb cabins of the New York Packet ships are finished with this wood and mahogany, and for richness and elegance are not to be surpassed.

A passenger on board of one of these ships was informed by the captain that it was with difficulty he procured sufficient in the city of New York to finish his cabin, and of a price exceeding that of mahogany.—Hallowell Geo.

ANALYSIS OF SOILS.

In our paper, vol. ii, p. 22, we intimated an intention to give the different modes of analysing soils, recommended by writers on husbandry, and now proceed to fulfil our promise. We would premise, however, that there is a process for this purpose, recommended by Sir Humphrey Davy, in his Lectures on Agricultural Chemistry, which is probably more accurate, but much more complicated than either of the modes which we here place before our readers. Sir Humphrey Davy's method requires a knowledge of chemistry which very few practical farmers have attained, and requires instruments of analysis which not many of our readers would be able or willing to procure. Besides, those gentlemen who have a wish to make use of his process have, generally, it is to be presumed, his treatise in possession. We therefore give a description of other processes, which are more simple, and we believe sufficiently accurate for all the common purposes of husbandry.

In the field to be examined, take earth a little below the surface, from four separate places, about 1-4 lb. avoirdupois from each. Expose it to the sun, or before the fire, till it is completely dry; and turn it over frequently that it may be well mixed together. From the heap take exactly four ounces, and pass this through a fine sieve, which will allow all the particles of sand and gravel to escape, but which will hold back stones, small fibrous roots, and decayed wood. Weigh the two parts separately, and take a note of each. The stones and other bulky materials are then to be examined apart from the roots and wood. If they are hard and rough to the touch, and scratch glass easily, they are silicious or flinty; if they are, without much difficulty broken to pieces by the fingers, and can be scraped by a knife to powder, they are aluminous or clayey; or if, when put in a wine glass and common vinegar poured upon them, small air bubbles ascend to the top of the liquid, they are calcareous. The finely divided matter, which ran through the sieve, must next undergo the test of experiment. After being weighed, agitate the whole in water, till the earth be taken up from the bottom and mechanically suspended, adding water till this effect be produced. Allow the mass then to settle for two or three minutes; and in that time the sandy particles shall have all sunk to the bottom. Pour off the water, which will then contain the clay in suspension, and the insoluble earth arising from animal and vegetable decomposition. The sand should first be attended to, and if from inspection it be thought either silicious or calcareous in its nature, the requisite tests may be instantly applied.—By this time the mixture will have deposited at the bottom of the vessel the clay, and other earths, with the insoluble animal and vegetable matter. After pouring off the water, dry the sediment, and apply a strong heat by placing it on the bottom of a pot ignited to redness, and the animal and vegetable matter will burn and fly off in aeriform products. The remainder lying in the bottom will be found to consist of clay, magnesia, or lime. To obtain accuracy, another 1-4 lb. of earth should be taken from the same heap, and the whole process gone over a second, a third, or even a fourth time, that the operator may rectify any blunders he had previously committed, and be satisfied as to the results of his experiment. He should provide

himself with a pair of fine scales and a set of weights divided at least into ounces and drachms. Although vinegar will detect lime by effervescence, it does not dissolve it so effectually as the nitric or muriatic acid; small quantities of which may be procured from the druggists at no great expense.—*Letters of Agricola.*

Process for analysing soils, given in Memoirs of the New York Board of Agriculture, vol. i, p. 7, of the Appendix.

1st. A quantity of the soil, including gravelly pebbles of the smallest kind, was pulverised in Wedgewood's mortar.

2d. Parcels of two hundred grains each, were separately weighed: three of them, if it was intended to ascertain the proportion of iron; two, if not.

3. One of the parcels was put into a crucible and heated gradually, constantly stirring it with a dry pine stick, until the stick become a little brownish from the heat, on pressing it against the bottom of the crucible.

4th. The above was then carefully poured into the scales and again weighed. What was deficient of the 200 grains, was set down as water.

5th. The parcel was then returned into the crucible, and heated to a high red heat. It was frequently stirred with a glass rod, and the heat was continued until the mass presented no shining particles. After allowing it to cool a little, it was returned into the scales again, and what it wanted of its last weight after being dried, was set down for the animal and vegetable matter. Part of this is undoubtedly water, but probably it is not more than should always be considered as attached to this part. It may here be added, that there will be no blackness in the appearance of the soil, if it is sufficiently heated.

6th. Let it now be poured in an assay glass, and add half a pint of pure water to it. After repeated stirring for ten minutes, let it stand for about three minutes, to allow the silicious matter to settle. Then pour off all which stands over the silicious part into another glass. Dry this sediment in a high red heat, weigh it, and set it down for the silice.

7th. Let the part which was transferred to another glass, stand until it settles, leaving the liquid part clear. Pour off the liquid into another glass; dry this sediment with a high red heat, weigh it, and set it down for the aluminous part.

8th. The remaining liquid was then evaporated in a glass evaporating dish. The solid residuum was scraped off, and weighed for the soluble salts.

9th. The other parcel of two hundred grains was put into a Florence flask, in which half a gill of equal portions of muriatic acid and water had previously been poured, and which had also been balanced by weights in the scale. After allowing it to stand about three hours, it was ascertained how much less than 200 grains was to be added to the weight, in order to balance the flask. This was considered as the weight of the carbonic acid that had been expelled. Then by the table of component parts, as 45 is to 55, so is this weight to the weight of the base. The carbonate of lime in the soil was thus ascertained. The lime, however, must now be subtracted from the silice, and the

weight of the carbonic acid must be deducted from the animal and vegetable matter; so the heat that burnt out the animal and vegetable matter, also expelled the carbonic acid, and the lime with the silice.

We are aware that part of the quick-lime may remain with the soluble salts, and part of the carbonic acid may still remain with its lime and the silice. The error, however, will be of no consequence in agriculture.*

Particular attention was paid to the time required for the alumine to settle. It was served, that in soils which are adhesive, and retain water a length of time, the time necessary for the alumine to settle, was in the same proportion. It was also found to be a much better criterion for determining the measure of this quality, than the actual proportion of lime.

Though the above method of analysis is sufficiently minute for the speculative chemist, yet it does not differ materially even from the most accurate method. Similar portions of soil taken from the river alluvion of William S. Esq. of Bethlehem, were analysed according to that of Sir Humphrey Davy, given in *Elementary Chemistry*. The results were as follow:

By the preceding formula.

Silice per cent.	6
Alumine,	2
Carbonate of lime,	3
Soluble salts,	1
Animal and vegetable matter,	1
Water,	1

By Davy's Method.

Silice,	60
Alumine,	22
Carbonate of lime,	3
Oxyd of iron,	2
Muriate of lime,	1
Sulphate of magnesia,	1
Animal and vegetable matter,	4
Water,	2
Loss,	3

AMOS EATON,
T. ROMEYN BECK.

The following mode of analysing soils is from "Treatise on Agriculture," first published the Albany Argus.

"1st. Take a small quantity of earth from different parts of the field, the soil of which you wish to ascertain, mix them well together and weigh them; put them in an oven, heat for baking bread, and after they are dried weigh them again, the difference, will show the absorbent power of the earth. When the loss weight in 400 grains, amounts to 50, this power is great, and indicates the presence of much animal or vegetable matter; but when it does not exceed twenty, the absorbent power is small, and the vegetable matter deficient."

2d. Put the dried mass into a vase with a fourth of its own weight of clear water, mix them well together; pour off the dirty water into a second vase and pour on as much clear

* It may, perhaps, be satisfactory to state, that the above formula was mentioned to Professor M'Neren, New York, who is now engaged in a very minute analysis of soils in that vicinity; and that he gave in his opinion, that the above method of analysis was the best adapted to the purpose for which the investigations were made.

† See Davy's chemistry.

ter as before; stir the contents, and continue the process until the water poured off, is as clear as that poured on the earth. What remains in the first employed vase is sand *silicious calcareous*.

3d. The dirty water, collected in the second vase, will form a deposit, which (after pouring the water) must be dried, weighed and *calculated*. On weighing it after this process, the quantity lost, will show the portion of *animal vegetable mould contained in the soil*: and, 4th. This calcined matter must then be carefully pulverised and weighed, as also the first deposit of sand, but without mixing them. To these apply, separately, sulphuric acid, and add that they respectively loose in weight, in the action of *calcareous or aluminous earths* contained in them. These last may be separated from the mass of soap lye, which dissolves them.*

Here is the light we wanted. In knowing the disease, we find the cure. Clay and sand purify each other; either of these will correct excess of lime, and magnesian earth, when treated with *carbonic acid*, becomes fertile."

ON THE CURCULIO.—BY DR. TILLOT.

The Curculio, a genus of insects belonging to the *Coleoptera*, or *Beetle* order. The species are said to be very numerous. The immense damage done, by an insect of this tribe, to the fruits of this country, of which there is no similar account in Europe, has given rise to a conjecture among some naturalists that we have a peculiar very destructive species in America.

The manner in which this insect injures and destroys our fruits, is, by its mode of propagation. Early in the spring, about the time when the fruit trees are in blossom, the *Curculiones* are in swarms from the earth, crawl up the trunks, and as the several fruits advance, they puncture the rind or skin, with their pointed beaks, and deposit their embryos in the wounds thus inflicted. The maggot thus bedded in the fruit, preys upon its pulp and juices, until in some instances, the fruit perishes, falls to the ground, and the insect escaping from so unsafe residence, makes a sure retreat into the earth: here, like other beetles, it remains in the ground, until a grub or worm, during the winter, is ready to be metamorphosed into a bug or beetle, to make spring advances. Thus every tree furnishes its own enemy; for although these bugs are manifestly the capacity of flying, they appear very reluctant in the use of their wings; and perhaps never employ them but when necessity compels them to migrate. It is a fact, that two trees of the same kind may stand in the nearest possible neighborhood, and not to touch each other, the one have its fruit destroyed by the Curculio, and the other be uninjured, merely from contingent circumstances, which prevent the insects from crawling up the one while they are uninterrupted from climbing the other. Why not tie a rope dipt in tar round the tree, and at the time when these insects begin to appear? The tar can be renewed. We strongly recommend the treatise on fruit trees, by Mr. J. B. Burlingame, New-Jersey.—T. C.] The Curculio delights most in the smooth-

stone fruits, such as nectarines, plums, apricots, &c. when they abound on a farm: they nevertheless attack the rough-skinned peach, the apple, pear and quince. The instinctive sagacity of these creatures directs them especially to the fruits most adapted to their purposes. The stone fruits more certainly perish by the wounds made by these insects, so as to fall in due time to the ground, and afford an opportunity to the young maggot to hide itself in the earth. Although multitudes of seed fruits fall, yet many recover from their wounds, which heal up with deeply indented scars. This probably disconcerts the Curculio, in its intended course to the earth. Be this as it may, certain it is, that pears are less liable to fall, and are less injured by this insect than apples. Nectarines, plums, &c. in most districts of our country, where the Curculio has gained an establishment, are utterly destroyed, unless special means are employed for their preservation. Cherries escape better, on account of their rapid progress to maturity, and their abundant crops: the Curculio can only puncture a small part of them, during the short time they hang upon the tree. These destructive insects continue their depredations from the first of May until autumn. Our fruits, collectively estimated, must thereby be depreciated more than half their value.

It is supposed the Curculio is not only injurious above ground, but also in its retreat, below the surface of the earth, by preying on the roots of our fruit trees. We know that beetles have, in some instances, abounded in such a manner as to endanger whole forests. Our fruit trees often die from manifest injuries done to the roots by insects, and by an insect more probably than the Curculio. In districts where this insect abounds, cherry-trees and apple-trees which disconcert it most above, appear to be the special objects of its vengeance below the surface of the earth.

We are unacquainted with any tribe of insects able to destroy the Curculio. All the domestic animals, however, if well directed, contribute to this purpose. Hogs, in a special manner, are qualified for the work of extermination. This voracious animal, if suffered to go at large in orchards, and among fruit trees, devours all the fruit that falls, and among others the curculiones in the maggot state, which may be contained in them. Being thus generally destroyed in the embryo state, there will be few or no bugs to ascend from the earth in the spring, to injure the fruit.

The ordinary fowls of a farm yard are great devourers of beetles. Poultry in general are regarded as carnivorous in summer, and therefore cooped sometime before they are eaten. Every body knows with what avidity ducks seize on the tumble-bug, (*Scarabeus carnificus*) and it is probable the Curculio is regarded by all the fowls as an equally delicious morsel. Therefore it is, that the smooth stone fruits particularly, succeed much better in lanes and yards, where the poultry run without restraint, than in gardens and other enclosures, where the fowls are excluded.

Even horned cattle, and all sorts of stock, may be made to contribute to the preservation of our valuable fruits. By running among the trees, they not only trample to death multitudes of these insects; but by hardening the ground, as in lanes, it becomes very unfit to receive or

admit such tender maggots as crawl from the fallen fruits. Besides, the Curculio is very timid, and when frightened by the cattle rubbing against the tree, or otherwise, their manner is to fold themselves up in a little ball, and fall to the ground; where they may be trampled and devoured by the stock, poultry, &c. Col. T. Forrest, of Germantown, having a fine plum tree near his pump, tied a rope from the tree to his pump handle, so that the tree was gently agitated every time there was occasion to pump water. The consequence was, that the fruit on this tree was preserved in the greatest perfection.

All the terebinthinate substances, with camphor and some others, are said to be very offensive to insects generally. Upon this principle, General T. Robinson, of Naaman's Creek, suspends annually little bits of board, about the size of a case knife, dipped in tar, on each of his plum trees. From three to five of these strips are deemed enough, according to the size of the tree. The General commences his operations about the time or soon after the trees are in full bloom, and renews the application of the tar frequently, while the fruit hangs on the tree. To this expedient he attributes his never failing success. Other gentlemen alledge, that common turpentine would be still better; being equally pungent, and more permanent in its effects. Some have sown offensive articles, such as buckwheat, celery, &c. at the root of the tree, and have thought that great advantages followed.

Ablation, or digging round the trees, and making bare their roots in winter, is an old expedient of gardeners for killing insects, and may answer well enough for a solitary tree, a year or two; but the Curculio will soon recover from a disturbance of this sort, and stock the tree again.

There is no surer protection against the Curculio than a pavement. This, however, is only applicable to a few trees. It may serve in town; but will not answer in the country. Flat stones may however be placed round the tree, and where lime is at hand, they may be cemented.

Many other expedients, such as smoking, brushing, watering, &c. may be successfully employed, for the protection of a favorite tree or two; but it is manifest, from the preceding history, that a right disposition of stock, especially hogs, among the fruit trees, can only be relied upon by a farmer, with orchards of considerable extent. And that the stock, poultry, &c. may perform the task assigned them, it is evidently that a proper disposition of fruit trees is essentially necessary.

As the smooth stone fruits are the grand nurseries of the Curculio, special care should be taken to have these effectually protected. Unless this can be done, a farmer should not suffer them to grow on his plantation. He will derive no benefit from them; and they will furnish a destructive vermin that will ruin his other fruits. Cherry-trees, nectarines, plums, apricots, &c. should therefore be planted in lanes and hard beaten yards, or paved yards, the common highways of all the stock of the farm, and not beyond the range of the ordinary domestic fowls. Orchards of apple trees, pear trees, peach trees, &c. should all be in one enclosure. The pear trees and peach trees may occupy

This method of analysing soils, is that described by Mr. Bosc, a member of the Institute of France, &c. recommended to French agriculturists.

corners of the whole design, so as occasionally to be fenced off. In large orchards, care should be taken that the stock of hogs is sufficient to eat up all the early fruit which falls, from May until August. This precaution will be more especially necessary in large peach orchards; for, otherwise, when the hogs become cloyed with the pulp of the peach, they will let it fall out of their mouths, and content themselves with the kernel, which they like the better; and thus the Curculio, escaping from their jaws, may hide under ground, until next spring. Solitary trees of one fruit or another, remote from the orchard, should be regarded as nurseries of the Curculio, and ought to be cut down or removed to the common enclosure. A young orchard should not be planted in the place of, or adjacent to, an old one, that it may not be immediately infested with the Curculio.

It is also apparent, from what has been said, that great advantages might result from an association or combination of the whole neighborhoods against this common enemy. Although an intelligent farmer may accomplish much, by due attention, within his own territory, the total extermination of the Curculio can hardly be expected, but by the concurrent efforts of whole districts.

NEW ENGLAND FARMER.

SATURDAY, SEPTEMBER 27, 1834.

Subscribers to the N. E. Farmer are requested not to pay any money to Travelling Agents, on account of the paper, as Agents of this description are not authorised to receive money on our account. Sept. 27.

Subscribers who have not paid for the first vol. of the Farmer, are requested to forward us the amount due immediately; and those who wish to save 50 cents must pay for the second vol. by the 1st of October.

REMARKS

On the Frothing or Foaming of Horses at the Mouth, in the fall of the year, called "Salivation of Horses," "Salivary Detractions of Horses," or "Slavers of Horses."

Every farmer is acquainted with this disorder, and therefore a description of its symptoms is not necessary. Of its causes and cure very little is known, perhaps nothing that can be relied on. Some have thought it was caused by the webs of spiders, some that it was a poisonous plant called *Lobelia*, or Indian tobacco, and a writer for the American Farmer, (Mr. Abel Seymour, whose communication we republished, p. 19, vol. ii.) thinks it is produced by "streaks of blue mould on the grass." Mr. Lovett Peters (whose communication on the subject is given p. 58) is of opinion that "the slavers of horses is caused by their eating a kind of grass of second growth, making its appearance in the fore part of July, much resembling oats, which come up in the fall after the crop has been taken off the ground, but has rather more of a brownish cast, and retains its green very late in the fall."

The acknowledged importance of the subject has induced us to give it such attention as our leisure and opportunities would admit of, and the result of our inquiry is an opinion that Mr. Peters is correct. In the 2d vol. of Memoirs of the Philadelphia Agricultural Society, (pages 320 to page 358) are published two communications "On the Salivary Detractions in Horses," written by the request of Mr. William Young, and by him forwarded to the Society. Mr. Abraham Perlee was the author of one of these communications, and Mr. William Baldwin of the other. Mr. Perlee attributes the disorder to a plant called "SPOTTED ERGOB,"

Euphorbia Maculata of Linnaeus." He says "the frequent occurrence of a profuse discharge of saliva from horses, and its rapid production of great debility and emaciation in that useful animal, had not only excited the attention and surprise of many of the farmers, but had also given rise to many conjectures as to the cause of it. Many opinions were founded on no substantial data, but originating only from conjecture; by many it was imputed to a peculiar quality inherent in the second growth of clover,—its generally appearing first when horses were put to pasture on the second crop, and being almost exclusively produced by pasturing in clover fields, were considered as corroborating evidences of the correctness of the hypothesis; but its not having occurred for many years after clover had been extensively cultivated, and not occurring at all in many places, where horses are pastured almost altogether on clover, sufficiently proved that opinion to be erroneous. It was also imputed to the effects of gypsum or plaster so frequently used to promote the growth of clover, but the occurrence of it on many farms where no plaster had been used, as well as its not occurring on many where it had been used very copiously, proved this opinion equally incorrect with the former.

My friend, Dr. William Baldwin, of Wilmington, informed me that a member of the Linnaean Society of Philadelphia had supposed, that the pytalism, (salivation) was caused by a species of *Euphorbia*, [scurge.] He also politely favored me with a specimen of the species to which it was imputed, and gave me some information on the *Euphorbia Americana* in general, which extensive knowledge in Botany enabled him to do. For the purpose of ascertaining the fact, I procured a small quantity of the *Euphorbia maculata*, and gave it to my horse enveloped in a small quantity of clover, carefully gathering stem by stem, and perfectly free from all other vegetable or any extraneous matter whatever. A preternatural discharge of saliva took place in less than half an hour. This experiment was frequently repeated, and invariably with the same result. To prove that clover did not contribute towards it, in some cases other grass was used as an envelope with the same effect. And when the horse was perfectly free from pytalism, a considerable quantity of clover carefully gathered without the *Euphorbia* was given to him, and no such effect was produced.

These experiments I considered sufficient to prove that the *Euphorbia maculata* could produce salivation. And I am induced to think, for reasons that I shall hereafter mention, that it is the general, if not the only cause of it."

[To be continued.]

Line believed to be an antidote against the Worm or Grub, which destroys potatoes.

We published in vol. ii, page 51, some remarks on a "large white worm with a red head," which attacks and devours potatoes in the hill, and requested information from our agricultural friends relative to the insect, and the means of guarding against its ravages. Since the publication of that article we have learnt that Mr. Young, in *Annals of Agriculture*, has the following passage:

"I planted an acre with kidney potatoes, and two days after ordered two bushels of fresh lime to be thrown over the surface of the ground, leaving two rows unplanted, to see if the experiment would have any visible effect on the crop.

"The latter end of August following, I was surprised to find the rows which were left unplanted very much grub eaten; and the remainder a fine, clear and perfectly sound crop. I planted four acres in 1782, dressing the whole with lime, and my crop was quite clear from the grub; fourteen acres in 1783 with the same

success, when a land, not top dressed with lime, suffered much, almost every plant being damaged."

It will be perceived that the amount of the top dressing in the first experiment mentioned was only about two bushels of lime to an acre, and if quick lime is an antidote against the grub that devours potatoes, it is probable that it may be equally effectual against the cut worm, wire worm, and other insects which so often destroy the hopes of the husbandman.

AGRICULTURAL EXHIBITIONS.

THE CATTLE SHOW. Exhibition of Manufactures, Ploughing Match, and sale of Animals and Manufactures, will be at Brighton, on the 15th and 16th Oct. No labor nor expense has been spared to increase the interest and extend the usefulness of this Farmers' and Mechanics' Festival. Much is anticipated, but we believe expectation will not transcend reality. At 9 o'clock, A. M. of Wednesday the 15th, the Member of the Massachusetts Society for promoting Agriculture will meet in their Hall for the admission of members &c. At half past 9, a procession will be formed by the Marshals, and proceed to the Meeting House, where Prayers will be offered by Rev. Dr. Foster, and the President will announce the arrangements, names of the several Committees on Premiums, &c.

The Worcester Cattle Show. &c. as we have already stated, will take place on the 8th of next month. We would now add that the Ploughing Match will commence at 9 o'clock, A. M. and immediately afterward a procession will be formed and proceed to the South Meeting House, where Prayers will be offered by the Chaplain of the day, and an Address will be delivered by a member of the Board of Trustees. The arrangements of this exhibition, as published in the Worcester papers, promise all that can be expected or desired to amuse, interest, gratify and improve.

The Berkshire Agricultural Society will hold the Cattle Show and Fair on the 1st and 2d of October at Litchfield. An Address will be delivered by a Member of the Society.

The Middlesex Cattle Show and Exhibition of Manufactures will be held at Concord on Thursday next. Prayers will be offered by the Chaplain, and an Address delivered by Josiah Adams, Esq. of Framingham.

Plymouth County.—The Exhibition will be at South Bridgewater, the 7th of October. Address by Hon. Kilborn Whitman.

The annual Show and Fair of the Hampshire, Franklin and Hampden Agricultural Society, will be on the 22d and 23d of October, at Northampton. We understand an Address will be delivered by I. C. Bates, Esq.

Cheshire Agricultural Society will meet at Westmoreland, N. H. on the 1st day of October. Address by Mr. John Lancaster, of Acworth.

COMMUNICATIONS.

MR. EDITOR.—If you or some of your correspondents would give some information, through the Farmer, relative to the best manner of cultivating the Currant bush, a favor would be conferred on one, and probably on several of your subscribers.

MR. EDITOR.—If you have not published it in your paper, I will thank you to publish an abstract of a law of this State, passed 12th June 1818, against "Trespasses in divers cases," stealing fruit, &c. from farms. A SUBSCRIBER.

By the Act alluded to it is enacted, Sect. 1. That any person shall enter upon any grass land, orchard, garden, without permission of the owner thereof, with intent to cut, destroy, take, or carry away, any grass, hay, fruit, or vegetables, with the intent to injure or deprive such owner; each person so offending shall forfeit and pay, for every such offence, a sum not less than two dollars nor more than ten dollars, to the use of the Commonwealth, to be recovered on complaint before any Justice of the Peace of the county in which the offence shall be committed; and the persons so offending shall also be liable in damages to the party injured.

Sect. 2. That if any person, having entered upon

ON FOUR CHEESE.

Hence Woburn dairy-wives run mad for cream,
And leave their milk with nothing but its name;
Its name devious and reproach pursue,
And strangers tell of "three times skimm'd sky-blue."
To cheese converted what can be its boast?
What but the common virtues of a post!
If drought o'ertake it faster than the knife,
Most fair it bids for stubborn length of life,
And like the oaken shield wherewith 'tis laid,
Mocks the weak efforts of the bending blade;
Or in the hog-trough rests in perfect spite,
Too big to swallow, and too hard to bite.
Inglorious victory! ye Cheshire meads,
Or Severn flow'ry dales, where plenty trades,
Was your rich milk to suffer wrongs like these?
Farewell your pride! farewell renowned cheese!
The skimmer dreads, whose ravages alone
Thus turns the mead's sweet nectar into stone.

BLOOMFIELD.

From the Bath Society Papers.

The Popham family were lords of Burnham, in Somersetshire, Eng. In the last century, and we have a tradition amongst us, that an ancestor of this family, when a young university blood, in company with two jovial companions, made too free with a gentleman's purse on the road. Soon after Popham repented, and his companions thought nothing less than a discovery would follow, which in order to prevent they led him into a wood, fastened his hands behind him, fixed one end of a halter round his neck, the other end to a limb of a tree, and in this situation left him seated upon his horse. Popham was under dreadful apprehensions of his approaching fate, and so much the more as the grass grew short on which the horse had for a time quietly fed; but he now began to stretch the rope by extending his circuit, and Popham, who had been humoring him with a jockey whistle, began to cry out in great agony of soul, *Ho! Ball! Ho Ball!* but at the very instant he was about to swing off, he was relieved by one of his companions, who had divided from the other and had returned back for that purpose. It happened that in a series of years Popham became a judge, before whom his companion who had saved his life was convicted for a capital offence, and being asked why judgment of death should not pass, he mimicked the judge's former tone of voice, and cried out *Ho! Ball! Ho Ball!* The judge, who now recollected his fate, told the Court that the prisoner appeared to be insane, and that he would respite sentence till next assizes, before which he found means to get the culprit pardoned and provided for.

Advantages of an Empty Purse.—People may talk as they please about independence. Your only real independent man is he of the empty purse. What is the rise or fall of stocks to him? What cares he for commercial failures? What for high or low prices? What for taxation or national debt? What for commotions, revolutions, the decline and fall of empires? Nothing. He smiles at the robber by night and the tax-gatherer by day, and regards the exciseman and pickpocket with equal indifference. He is your free philosopher, worthy of the eye of Jove—one, who stands

"Unhurt amid the war of elements,
The wreck of matter and the crush of worlds."

The following curious passage occurs in Capt Franklin's Journey to the Polar Sea. The Quarterly Reviewer says that he "recollects a case stated by Humboldt, in South America, perfectly well authenticated, and almost precisely similar to it."

"A young Chipewyan, had separated from the rest of his band for the purpose of trenching beaver, when his wife, who was his sole companion, and in her first pregnancy, was seized with pains of labor. She died on the third day after she had given birth to a boy. The husband was inconsolable, and vowed in his anguish never to take another woman to wife, but his grief was soon in some degree absorbed in anxiety for the fate of his infant son. To preserve his life he descended to the office of nurse, so degrading in the eyes of a Chipewyan, as partaking of the duties of a woman. He swaddled it in soft moss, fed it with broth from the flesh of the deer, and to still its cries applied it to his breast, praying earnestly to the great Master of life to assist his endeavours. The force of the powerful passion by which he was actuated, produced the same effect in his case, as it has done in some others which are recorded, a flow of milk actually took place from his breast. He succeeded in rearing his child, taught him to be a hunter, and when he attained manhood, chose him a wife from the tribe. The old man kept his vow in never taking a second wife himself, but he delighted in tending his son's children, and when his daughter-in-law used to interfere, saying that it was not the occupation of a man, he was wont to reply, that he had promised to the great Master of life, if his child was spared never to be proud, like the other Indians. He used to mention too, as a certain proof of the approbation of Providence, that although he was always obliged to carry his child on his back while hunting, yet that it never roused a moose by its cries, being always particularly still at those times. Our informant added that he had often seen this Indian in his old age, and that his left breast, even then, retained the unusual size it had acquired in his occupation of nurse."

From a Manchester (Eng.) paper of May 6.

On Thursday last, Mr. Francis Wooton, the person who has contracted to remove the ball and cross of St. Mary's spire, by means of ladders only, arrived in this town, accompanied by his son and an assistant, in order to take advantage of the first favorable weather to carry his wonderful project into effect.

After making the necessary preparations he commenced the erection of his chain of ladders against the spire on Friday morning, and before the close of that day he had succeeded in reaching within a few yards of the ball, in a manner the expedition and ingenuity of which were in the highest degree admirable. The method by which he contrived to erect ladder upon ladder, in a way sufficiently secure, was as follows:—After having placed one of the longest against the base of the spire, he fastened the top of it to the masonry by new clamps; then by means of a block and pulleys, attached to the upper part of this ladder, his assistants below were enabled to raise another one, whilst Mr. Wooton followed and guided it in the proper direction: thus making it appear to the spectators below as if he were pushing the ladder before him,

with the more force of his arms. When this ladder was elevated to the requisite height, he proceeded, by means of cords, to secure the bottom part of it firmly to the top part of the lower one, and then ascended the one last raised, and fastened the end of it also by means of clamps—thus proceeded, by alternately removing the pulleys, a ladder higher each time. As he ascended, and his situation became consequently more perilous, the anxiety evinced by the crowds of spectators collected below became intense, being careful to avoid making any noise for fear the sound should distract his attention, and endanger him to be precipitated headlong.

On Saturday morning, we arrived in the church-yard as Mr. W. was raising the last ladder, by far the most perilous of the whole, and had an opportunity of surveying him through a powerful telescope, and to see the composure and confidence he proceeded with his work when the least slip would have hurled him to destruction, was truly astonishing. When he had fastened the bottom of this ladder, which was placed against the ball in a nearly perpendicular direction, he had to ascend it though unfastened at the top; and in this dangerous situation he contrived to throw a rope twice round the spire, and succeeded at last in making it perfectly secure; after which he mounted to the top, stood on the very pinnacle of the spire, and pulling off his hat, gave three cheers which were heartily echoed from the crowd below, who had for a long time been looking up with breathless astonishment and fear. On his descent, he was again hailed by the cheers and congratulations of the bystanders. During the remainder of that day he was not able to proceed much farther in his undertaking, in consequence of the wind being too high to render it practicable. By means of a hook fastened to his belt, he was enabled to attach himself to the ladder when at work, but this not being visible to the spectators, his situation at times seemed hazardous in the extreme, when both his hands were engaged, and there appeared no other stay between him and destruction than the uncertain footing of the ladder.

Of the undertaker and his project we can scarcely speak in terms too high; and we believe it equals, if not exceeds, any thing in the records of human daring and enterprise. To the time of our paper going to press, the weather had continued too unfavorable to render further proceeding in the undertaking, up to that period, practicable.

Counsellor Lamb, an old man, when the present Lord Erskine was in the height of reputation, was a man of timid manners, and nervous disposition, and usually preaced his pleading with an apology to that effect, and on one occasion, when opposed in some cause to Erskine, it happened to remark that "he felt himself growing more and more timid as he grew older." "No wonder," replied the witty but relentless barrister, "every one knows the older a lawyer grows the more sheepish he becomes."

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but the who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

ON MAKING AND PRESERVING CIDER.

Although so much has been published on this subject that every farmer who derives any part of his knowledge of agriculture from reading, must be supposed to be acquainted with such of the details as can be derived from the press of a printer; yet we hope that a recapitulation of well known rules on a topic of such interest will prove useful. If we fail to communicate original ideas, we may be of service by putting some people in mind of what they knew before, and might overlook in the hurry of business.

The first step towards making good cider is to procure good fruit. This fruit should be of one kind, or the juice of each kind should be pressed and preserved by itself. "The value of fruits, for the manufacture of cider may be judged of from the specific gravity of their expressed juices. The best cider and perry are made from those apples and pears that afford the densest juices; and a comparison between different fruits may be made with tolerable accuracy, by plunging them together in a saturated solution of salt, or a strong solution of sugar: the one that sinks deepest will afford the richest juice." * The Complete Farmer's Dictionary says, "The worse the apple is for the table, the better it is in general for cider. The more the apple is in its kind, the fitter it is for cider; that is to say, if it is at all fit; for I have seen an apple of a very deep red, which was nothing for that purpose. A sweet apple with a tough rind will always yield a good vinous juice. The more yellow the flesh of the fruit, the better and finer colored the cider will be." The apples which are intended to make cider of the best quality should be perfectly ripe, and clean. None should be ground together but such as are of about an equal degree of ripeness. They should not be allowed to remain in a heap till the life or spirit of their juice is lost, and they become insipid and *malic*; and as a general rule they may be said to be in the best state for making into cider, when they are of that degree of ripeness which makes them pleasing to the palate; or, as the Complete Farmer's Dictionary says, "the fruit should be ground when it is in the greatest perfection for eating."

The apples should be spread on a floor, covered, and protected from the weather, for the purpose of sweating. When the weather is cold and warm they should be permitted to remain in this situation four or five days; but if the weather is wet and cool, they should be a day or two longer. They should then be picked over, wiped and dried in the sun, and those

which are rotten or otherwise defective, thrown away. 4. Apples which drop early, commonly called wind falls, or those which are not ripe, or of inferior quality, may be made into an inferior kind of cider, which is sometimes submitted to the still, by which cider-spirit is obtained for mixing with store cider, and other purposes. 5. The cooler the weather in which your cider is made, provided it does not freeze your fingers nor your pomace, the better; and it is recommended to choose a time when the wind is from the west or north. Cider intended for spring and summer use should be made the latter part of October, or still later if the season will permit. 6. The cider-mill, press, grinding mill, trough, and other implements should be perfectly sweet and clean. Some farmers tell us that cider will work itself clear, and therefore a little want of cleanliness in making it does no harm. But the truth is that cider receives any offensive, unpleasant, or unhealthy taint, and communicates it as soon as any liquor. The pomace should be laid on the press in clean straw, without using any water. 7. The finer apples are ground the more cider they will yield. If the mill is well fitted it crushes the seed, and gives a peculiar and pleasant aromatic bitter to the must which becomes the more perceptible as the cider acquires age. 8. The trough to hold the pomace should be large enough to contain a whole cheese at once. The pomace may stand from six to twenty-four hours, according as you wish to give a higher or paler color to your cider. But it should be stirred frequently if the weather is warm to prevent fermentation. Joseph Cooper, Esq. of New Jersey, says, "the longer a cheese lies after having been ground, before pressing, the better for the cider, provided it escapes fermentation before the pressing is completed."

9. The first running from the press, if you should have your cider of the first quality, should be put by itself. Some have gone so far as to keep separate that which is obtained without pressing. An English farmer says "as fast as the fruit is ground (I need not say I use the ripest first) the pulp is put into the cheese; at the bottom of the vat is a tap through which a considerable quantity of vinous juice will run without pressing. This is the best cider, and I barrel it separately." The Farmer's Assistant, however, says "the first and last running of a cheese should be put by itself, as it is not so good as the rest."

10. "When the pressing of the apples is finished the most careful makers of cider strain it through a hair sieve, a coarse cloth, or sand, to separate it from the coarsest dregs. It must then be left to itself till it has gone through the necessary fermentation; for this purpose some put it into hogheads, and others into great tubs or vats, wide at top and narrower at bottom, containing from five to twenty hogheads. In these vessels the heaviest lees subside, and the lighter lees form a crust, which, when it begins to crack and sink gives notice of the time to draw off and barrel the cider. This is the Eng-

lish practice in general, but our farmers most usually dispense with vats, or vessels merely for the purpose of containing the must while fermenting. They put it directly into the barrels or casks in which it is intended to remain at least till racked off some time in the winter or spring. It is then deposited in a cool cellar, and the bung is usually left out of the barrels till the fermentation begins to subside. The bungs are then driven in tight, leaving a small spigot vent a while longer if necessary, when at length the spigot hole is closed and the vessel made perfectly air tight.

11. There are three fermentations of which cider is capable, viz. the *vinous*, which produces the alcohol, that gives the liquor its stimulating and exhilarating qualities; the *acid*, which turns the cider to vinegar, and the *putrid*, which totally destroys its spirit and texture and reduces it to a nauseous and poisonous liquid. The principal object in making good cider is to stop the *working* of the cider as soon as the *vinous* fermentation is completed. There are several modes by which this may be effected. The first mode is to have the vinous fermentation conducted in vessels air tight, or as nearly so as possible; thus preventing the escape of carbonic acid or fixed air, which gives it life, and causes its briskness. Cider cannot become vinegar unless it can give out carbonic acid gas, [fixed air] and receive oxygen gas [vital air] (which is the principle of acidity) from the atmosphere. If the fermentation proceeds slowly, especially in air tight vessels, the liquor is impregnated with carbonic acid, which under different circumstances would make its way into the open air. It has been a practice to pour a tumbler of oil into the bung hole of every cider cask. This entirely excludes the oxygen of the atmosphere from access to the liquor to turn it sour, and in part confines the carbonic acid which gives it life, and makes it brisk and sparkling. Another practice is to confine, by main force, the carbonic acid to the fermenting cider. Dr. Darwin says he was told by a gentleman who made a considerable quantity of cider on his estate that he procured vessels of stronger construction than usual, and directed the apple juice, as soon as it was settled, to be bunged up close, and that though he had one vessel or two burst by the expansion of the fermenting liquor, yet this rarely occurred, and that his cider never failed to be of the most excellent quality and was sold at the highest price. New cider may likewise be stopped in vessels of no more than common strength and buried pretty deeply in the ground, or immersed in spring water, in which situation we are told that it may be kept for years, and be very fine when taken up.

12. It is likewise said that a handful of powdered clay, or a quarter of a pound of salt petre, or the same quantity of alum put into a barrel of cider when fresh from the press, or before the fermentation has begun will so check and regulate that process that the barrel may be stopped tight immediately, and then will retain all its fixed air.

TO BE CONTINUED.

BRIGHTON CATTLE SHOW.

Although we have already published, vol. i, p. 273, an official account of the premiums offered to the competitors at this exhibition, we think it cannot be amiss to give the following from the Columbian Centinel, which is judiciously abridged, and may accommodate some of our subscribers, who are not in possession of our first volume.

The Cattle Show, Exhibition of Manufactures, Ploughing Match, and the Public Sale of Animals and Manufactures, at Brighton, under the direction of the Trustees of the Massachusetts Society for the promotion of Agriculture, encouraged by the patronage of the Legislature, will be on Wednesday and Thursday, the 15th and 16th of the present month of October, to commence on each day at 9 o'clock, A. M. Some months since, the Trustees circulated throughout the State, a full sheet of their Premiums and Regulations, many of which it is not necessary now to repeat, as experiments for competition have been made. We therefore need only give a selection of some, and a summary of other Premiums, which it is believed are the most liberal offered in this, or any other State.

PREMIUMS FOR STOCK.

For the best Bull, raised in Massachusetts, above one year old, \$30; next best do. do. \$20; next best do. do. \$10.—For the best Bull Calf, from 5 to 12 months old, \$15; next best do. do. \$10; next best do. do. \$5.—For the best Cow, not less than 3 years old, \$30 next best do. do. \$20; next best do. do. \$10.—For the best Heifer, from 1 to 3 years old, with or without calf, \$15; next best do. do. \$10; next best do. do. \$7.—For the best Ox, fitted for slaughter, regard to be had to the mode and expense of fattening, \$30; next best do. do. \$25; next best do. do. \$15.—For the best pair of Working Oxen, \$30; next best do. do. \$25; next best do. do. \$20; next best do. do. \$15; next best do. do. \$10.—For the best Spayed Heifers, not less than one year old, \$25.—For the best Spayed Sows, not less than four in number, and not less than five months old, \$20.

[The claimant to be entitled to either of these two last premiums, must state, in writing, the mode of operation and treatment, in a manner satisfactory to the Trustees.]

For the best Merino Wethers, not less than six in number, having respect to form and fleece, \$15; next best do. do. \$5.—For the best Native Wethers, not less than six in number, do. \$10; next best do. do. \$5.—For the best Merino Ram, do. \$15; next best do. \$10.—For the best Merino Ewes, not less than five in number, do. \$20; next best do. do. \$10.—For the best Boar, not exceeding two years old, \$12; next best do. do. \$8; next best do. do. \$5.—For the best Sow, \$12; next best do. do. \$8; next best do. do. \$5.—For the best Pigs, not less than two in number, nor less than four months old, nor more than eight, \$10; next best do. do. \$5.

[None of the above animals will be entitled to premiums, unless they are wholly bred in the State of Massachusetts.]

For the best Ram which shall be imported into this State, after this advertisement, and before the 15th day of October next, of the improved Leicester breed of long woolled sheep, \$75, or a gold medal of that value, at the option of the importer; next best do. do. \$50.—For the best Ewe, of the same breed, imported under the

same terms, and for the like superior qualities, \$60; next best do. do. \$40.—To the person who shall import into this State, from Europe, a Male and Female Goat, of the pure Cashmere breed, \$100.

The persons claiming these premiums to engage to keep the imported animals within the State.

No animal, for which to any owner one premium shall have been awarded, shall be considered a subject for any future premium of the Society, except it be for an entirely distinct premium, and for qualities different from those for which the former premium was awarded.

Any of the above Stock, when raised and still owned at the time of the exhibition, by the person who raised them, will entitle the claimant to an allowance of ten per cent. in addition. But Sheep, to be entitled to any of the above premiums, must be raised by the person entering them.

Here follow thirty-nine premiums of from five to thirty dollars each, (the total amounting to \$597,) for various AGRICULTURAL EXPERIMENTS, for raising Indian Corn, greatest quantity of Vegetables, Wheat, Barley, Millet, Carrots, Potatoes, Beets, Parsnips, Mangel Wurzel, Ruta Baga, Turnips, Onions, and Cabbages. Also, for experiments on "Soiling Cattle;" turning in Green Crops for manure; ascertaining the best season for laying down land for Grass; for raising Dry Pigs and Beans, and Flax, for taking up good Honey; and the best management of Bees; for the best Cheese and Butter, the best Cider and Currant Wine, and to ascertain the utility and comparative value of the Cobs of Indian Corn, when used with or without grain itself, ground or broken.

The Regulations require, in addition to others, that in relation to all vegetables, except Potatoes, Onions, and common Turnips, the fair average weight of at least twenty bushels must be attested; and if there be hay scales in the town in which raised, not less than three average cart loads must be weighed.

The claims under this head, together with the evidences of the actual product, must be delivered, free of expense, to BENJAMIN GILES, Esq. of Boston, Assistant Recording Secretary, of this Society, on or before the first day of December next—the Trustees not intending to decide upon claims under the head of Agricultural Experiments, until their meeting in December.

FOR INVENTIONS.

Premiums from 20 to 30 dollars are offered to the person who shall have most successfully used the *Drill Plough*; or who shall have invented the best *Machine for Pulverizing Plaster*; and to any one who shall produce any Agricultural implement, of his own invention, and which in the opinion of the Trustees shall be deserving of a premium. Persons who have taken out Patents for their inventions are not thereby excluded from competition.

FOR FOREST TREES.

These premiums are one of \$100, and three of \$50 each, for the best plantation of *White Oak Trees*, to be raised from the acorn, not less than 1000 trees per acre; the best do. of *White Ash* and *Larch Trees*, raised from the seeds, not less than 1000 per acre; the best Orchard of *Apple Trees*, not less than 100 in number, planted since the spring of 1815, and to be inspected

in 1827; and for the best *Live Hedge*, made either of White or Cocksput Thorn, planted in 1820.

FOR DOMESTIC MANUFACTURES.

Ten premiums of from five to twenty dollars, for best specimens of fine Broadcloth, best superintine and second best Cassimere and Satinets, best Sole Leather, and best dressed Cal Skins.

FOR HOUSEHOLD MANUFACTURES.

Thirty-one premiums, of from 3 to 20 dollars each, for Woolen Cloth, double and milled Kersey, Coating, Flannel, Carpeting, Stair Carpeting, Blankets, Woolen Knit Hose, Worsted Hose, and Half Hose, Woolen Gloves, Linen Diaper, Table Linen, Sewing Silk, Linen Cloth, and for the best specimen of any Cotton fabrics in private families, not less than five pieces.

All the above Manufactures (except where of cotton) must be of the growth and manufacture of this Commonwealth. Animals, Manufactures, or Articles, may be offered for premium at Brighton, notwithstanding they may have received a premium from a County Agriculture Society. Persons who prefer medals to money may have their option; and the Trustees may award either one of the Society's gold or silver medals in lieu of pecuniary premiums. The premiums to be paid within 10 days, and those not demanded within six months will be deemed as having been gratuitously given to aid the funds of the Society.

PLOWING MATCH.

On THURSDAY, the 16th, Premiums will be given to the owners and ploughmen of three Ploughs, drawn by one yoke of oxen, which shall be adjudged, by a competent Committee, to have performed the *best work, at least expense of labor*, not exceeding half an acre to each plough. Notice has been given, that a piece of ground has been provided for twenty ploughs—ten double and ten single teams; and that entries may be made of the names of the competitors until the morning of the 15th. Preference will be given to those who enter first; but if, on counting the list at the hour appointed, precisely, those first named do not appear, the next in order will be preferred. There will be two Committees, of three persons each—one to be the judges of the ploughing by the double teams, the other of the ploughing by the single teams—the latter to have assigned to them a part of the field distinct from that of the double teams.

Premiums as follows, (being the same for the double and single teams.)

First Plough \$15, Ploughman 3, Driver 4. Second Plough \$10, Ploughman 5, Driver 3. Third Plough \$5, Ploughman 3, Driver 2.

In each case, if there be no Driver, both sums to be awarded to the Ploughman.

The persons intending to contend for the Prizes, must give notice, in writing, to S. W. Fomeroy, or Gorham Parsons, Esqrs. of Brighton. The competitors will also be considered as agreeing to follow such rules and regulations as may be adopted by the Committee, on the subject. The Ploughs to be ready to start at 6 o'clock, A. M.

The result of the last Ploughing Matches at Brighton, and the satisfaction expressed by many of their agricultural brethren, will induce the Society to continue these premiums annually.

in connexion with the Cattle Show, as an efficacious means of exciting emulation and improvement in the use and construction of the most important instrument of agriculture.

Persons intending to offer any species of Stock for premiums, are requested to give notice in proof, either by letter (post paid) stating the article, or to make personal application to Mr. Nathan Winship, at Brighton, on or before the 14th day of October, and requesting him to enter such notice or application, so that tickets may be ready at 9 o'clock on the 15th. No person will be considered as a competitor, who has not given such notice, or made such application for entry, on or before the time above specified.

All articles of manufactures and inventions, shall be entered and deposited in the Society's Rooms, on Monday, the 13th of October, and will be examined by the Committees on Tuesday, the 14th, the day before the Cattle Show; and no person but the Trustees shall be admitted to examine them before the Show. The articles so exhibited, must be left till after the Show, for the gratification of the public.

The applicants will be held to a rigid compliance with this rule relative to entries, as well as the other rules prescribed.

The examination of stock, (except working oxen) will take place on the 15th, and the trial Working Oxen, examination of Inventions, and Ploughing Match, on the 16th of October.

The Trustees also propose to appropriate, on the second day of the Cattle Show, their Pens to the public sale of any Animals, that have been offered for premium, and also of any others. It is considered by them, as possessing fine qualities; and their Halls for the public sale of Manufactures. Both sales to take place at half past eleven o'clock, precisely. And for all Articles or Manufactures, that are intended to be sold, notice must be given to the Secretary, before 10 o'clock of the 16th. Auctioneers will be provided by the Trustees. By order of the Trustees,

R. SULLIVAN,
J. PRINCE,
G. FARNSON, } Committee.
E. H. DERBY, }

Rules and Regulations, to be observed at the Cattle Show, Exhibition of Manufactures, Ploughing Match, and Public Sale of Animals and Manufactures, at Brighton, on Wednesday the 15th and Thursday the 16th of October, 1823.

—At 9 o'clock, A. M. of Wednesday the 15th, the Members of the Massachusetts Society for promoting Agriculture, will meet in their Hall for the admission of members, &c. At half past 10 o'clock, a procession will be formed by the Marshals, to proceed to the Meeting House, where the Ploughing Match will be offered by Rev. Dr. Foster, and the President will announce the arrangements, and the names of the several Committees on premiums. Immediately after they will proceed to their several duties.

—All Stock entered for Premium, must be in the Pens at 8 A. M. according to the numbers on their Tickets, as furnished by the Secretary, and under the direction of the Marshals.

I.—Gentlemen who have Fine Animals, not entered for Premiums, will gratify the Society by exhibiting them in their Field, where Pens will be allotted to them, subject to the same rules with those who contend for premiums.

IV.—No Animal can be removed from the Pens, but by permission of a Marshal or Trustee.

V.—The avenue between the ranges of Pens, is intended exclusively for the Trustees, Committees, Members of the Society, and invited persons; it is therefore requested and expected, that no other person enter the same, but at the invitation of one of the Trustees; but the Field will be free to all.

VI.—All Articles, under the head of "Domestic and Household manufactures," it must be carefully noticed, are to be deposited in the Society's Rooms, on Monday the 13th, to be examined by the committee on Tuesday the 14th, being the day before the Cattle Show. Persons offering them, will hand to the Secretary, the necessary Certificates of the growth of the Wool and Flax, and of the Manufacture, being within the State of Massachusetts, as they are not permitted themselves to be present at the examination by the Committee; but they are expected afterwards to see to their own goods, which are not allowed to be removed from the Hall until after the public sale on the 16th.

VII.—All persons offering Articles under the head of "Inventions," will place them in the Lower Hall, on the West Side, as directed by the person who will be there to receive them, on Monday the 13th, and on Tuesday the 14th, at 9 A. M. they will attend the Committee, furnished with evidence of their usefulness, &c. agreeably to the premium list.

VIII.—All persons offering Butter, Cheese, Cider, and Currant Wine, must have them at the Hall on Monday the 13th or before 10 A. M. of Tuesday the 14th, all having a private mark, and a sealed paper, giving a full statement of the Cider and Wine making. The best barrel of Cider and gallon of Currant Wine, which obtain the first premium, will be made use of at the Society's Dinner, on Wednesday the 15th.

IX.—Those persons offering Working Oxen (having regularly entered them) will arrange them in the Society's Field, under the direction of a Marshal, and must thereafter be under the direction of the Committee for that purpose.

X.—Those persons who have entered ploughs for the Matches as well as those who intend so to do before 9 A. M. of the 16th, will please observe the new regulations on that head in the premium lists, and have their ploughs on the ground before 9 o'clock, as precisely at that hour the lists will be called over.

XI.—The following Gentlemen being appointed Marshals, Col. Lusher Gay, Maj. Wheeler, G. W. Beale, Esq. Col. S. Jaques, and Capt. Isaac Cook, it is expected that every person having business at the Show, will follow their directions, as also those of the Trustees of the Society, so that proper order and regularity may be supported.

XII.—As the Chairman of each Committee will prepare their own Rules and Regulations, it is expected and required, that all persons having business with either Committee will govern themselves accordingly.

XIII.—The Premiums will be awarded on the 16th, at 4 P. M. in the Meeting House, and the Treasurer will immediately after, in the Society's Hall, pay all premiums, those the most distant from home first. It must be remembered that any premiums which are not claimed in Six Months, are considered as generously given to aid the funds of the Society.

XIV.—The examination of all Animals will

take place on Wednesday the 15th; the trial of Working Oxen and Ploughing Matches on Thursday the 16th; and the Public Sales of Animals and Manufactures on Thursday the 16th.

XV.—All Fat Animals must be weighed before entering the Pens, at the expense of their owners.

XVI.—Animals to be sold at Public Auction on the 2d day of the Show (agreeably to notice in the Hand Bill for premiums) must be entered, and a description of the same given the Secretary on the 15th, to enable them to enter the proper Pens on the morning of the 16th, the sale whereof will commence in regular order at half after 11 o'clock precisely. An Auctioneer will attend to the sale, free of charge to the owners, who must be responsible for the delivery of their own animals, in conformity to the conditions of the sale. The sale of Manufactures will commence in the Hall at 12 o'clock. Proprietors of Goods will have a list prepared to hand to the Auctioneer; they are also expected to collect their own monies: it being fully understood, that the Auctioneer is only to bid off the same, free of any expense; and the sale will commence with the first entry, and proceed on regularly.

XVII.—Any members of the Society who have not received their Certificates, will find Mr. Kuhn attending for that purpose, at their Office in the Agricultural Hall, who will deliver them, on payment of Five Dollars, the sum agreed upon instead of all annual assessments. The same person will also on application in season, furnish Tickets for the Dinner at the old Bull's Head Tavern.

XVIII.—The Hall will be opened on Wednesday the 15th, between the hours of 9 and 12, for the sole purpose of giving Ladies an opportunity of viewing the Manufactures, and some of the Trustees will be there to wait upon them; and the owners of goods are expected, on both public days of Show and Sale, to attend to and exhibit their own articles. The Trustees can devise no better mode to prevent loss and damage to goods, and at the same time give the public an opportunity to view them.

XIX.—No person whatever will be admitted into the Halls only on Wednesday the 15th, and Thursday the 16th, except those having business there.

September, 1823.

Method of preserving Grapes.—Take a cask or barrel, inaccessible to the external air, and put into it a layer of bran, dried in an oven, or of ashes well dried and sifted. Upon this, place a layer of grapes well cleaned, and gathered in the afternoon of a dry day, before they are perfectly ripe. Proceed thus with alternate layers of bran and grapes, till the barrel is full, taking care that the grapes do not touch each other, and to let the last layer be of bran; then close the barrel, so that the air may not be able to penetrate, which is an essential point. Grapes, thus packed, will keep nine or even twelve months. To restore them to their freshness, cut the end of the stalk of each bunch of grapes, and put that of white grapes into white wine, and that of black grapes into red wine, as you would put flowers into water, to revive or keep them fresh.

The following is quoted with approbation in a work published the present year, in Edinburgh and London, entitled, "*Journal of a Horticultural Tour through some parts of Flanders, Holland, and the north of France, by a Deputation of the Caldonian Horticultural Society.*" We had before observed, that orchards commonly flourished remarkably, and were unusually fruitful on the sides of hills, and other uneven ground; but had formed no conjecture respecting the cause of this singular effect, which, we think is satisfactorily explained by what is here presented. **EDITOR.**

On the Advantages of planting Fruit Trees on Declivities, in a letter from the Rev. John Walker to Lord Kames, dated Moffat, Feb. 18, 1773.

Dodart first observed that trees pushed their branches in a direction parallel to the surface of the earth. If a tree stands on a steep, it pushes both towards the hill, and towards the declivity; but on both sides it still preserves its branches parallel to the surface. As there is an attraction between the upper surface of leaves and light, I am also persuaded, though not equally certain of it from experiment, that there is an attraction of the same nature between the under surface of leaves and the surface of the earth. This I consider as the cause of the phenomenon.

I had long observed, that the most fruitful orchards, and the most fertile trees, are those planted on a declivity, and the steeper it is, though not quite a precipice, the more fertile will they prove. But I was never satisfied as to the cause of it, till I called to mind the above observation of Dodart; which occurred to me when I was in the town of Jedburgh. There is more fruit about that place, and more fruit-bearing wood upon the trees, than I have seen in any other part of Scotland; but its orchards and fruit-gardens are mostly situated in very steep places.

It is well known that the spreading of trees always renders them fruitful. On a plain, however, they incline to shoot upwards; and therefore art is called in by skillful gardeners, and applied in various ways to check their perpendicular, and to promote their lateral growth. But this point, which can only be gained upon a plain by art, is obtained upon a declivity by nature. There a tree loses its tendency to shoot upwards, and in order to preserve its branches parallel with the surface, is constrained to put them in a lateral direction.

Hence an important rule in the choice of orchards and gardens.

From the Brattleborough Messenger.

Observations on the construction of Farm Buildings, Gardens, &c.

It is not the design of the writer to give a general plan of all the buildings necessary for a farmer to carry on his occupation to advantage; but merely to give a few hints which strike him as worth noticing.

OF THE HOUSE.

It is very desirable, in our cold climate, to construct our houses so as to guard as much as possible against the inclemency of the winter, with the least possible degree of fuel. *1st.* Our kitchens and sitting rooms ought never to have a door open directly from the open air. By having a small entry on the inside of the house, or a porch without, an atmosphere is created of a medium temperature between the air of the

room in which the fire is, and the outward air; and consequently much cold air is prevented from getting into the house. *2d.* It is a good plan to have the staircase between the upper and lower rooms tightly enclosed: by this means the torrent of cold air that comes down from our chambers to our lower rooms, would in a great measure be prevented. Those who have made use of a good cooking stove, and have got thoroughly acquainted with the comforts of it, will seldom be persuaded to part with it at scarce any price. Thomson's, James' and Connel's stoves are all good patterns. The Lenox stove, so called, from being cast at Lenox, Mass. having the oven underneath, is much liked. The Putney stove is good except for large rooms; it consumes a good deal of fuel: if it had some pipe to it, I should like it better, but those who have them admire them for cooking. For those farmers who make economy a great object, it is an excellent plan to have the pipe of the kitchen stove go through the sitting room.

OF THE WORK SHOP.

It is of very great importance to a farmer to have a shop in which he can work in rainy weather and in the winter season. Every farmer should be something of a mechanic: a very little experience will enable him to use the most common carpenter's and joiner's tools. A small farmer who sends for a mechanic to do every little job, must expect to die poor: few are so improvident. But I would not stop here—I am convinced that most of our farmers would make more money if they made a point of carrying on some mechanical business in the winter.

New England farmers, as a class of people, are perhaps the most ingenious in the known world; but from the fall to the spring little comparatively is to be done in agriculture, and consequently, they do but little. What they get in the summer they too often spend in the winter by contracting a habit of lounging in stores and taverns. "*When people have nothing to do the Devil sets them to work.*" To improve our short summers to advantage, most farmers in the winter should be mechanics, and most of our mechanics in the summer months should be farmers:—This would have a wonderful effect to preserve their constitutions. Our shoes, hats, clothes, ploughs, carts, sleds, and indeed all our implements of agriculture and most kinds of household furniture should be made in winter.

FEEDING STOCKS.

As a further improvement in the feeding of cattle, I would recommend that the shucks [husks] be well wet with brine, as they are stowed away in the fall. This was recommended to me last winter, and was done in this way: as many shucks were thrown in the house at a time, as would raise it six inches, after being well trod down; as soon as they were sufficiently trod, the surface was well sprinkled with brine; as many more were then put in, and the same process observed, until the whole were put away. In this way one bushel and a half of salt were applied to the shucks taken from a hundred bushels of corn, and the consequence was, my shucks were heartily eaten by my cattle, and until last winter, they never would eat them, as long as they could get pea vines. This is not all the advantage resulting from salting them; it was very evident that they were ren-

dered much more nourishing, as the dry cattle which were fed on the shucks alone, were in nearly as good order as those which were fed on the vines. To do this properly, they should not be made so wet as to heat and mould. The expense need not be counted at all, as cattle, while these shucks are given them will require no other salting.

As there is so little economy observed in fattening hogs in this part of the country, I beg leave to notice this subject, and point out a better and cheaper mode. The common practice is to put them in a large pen and throw the corn on the ground; in a wet season, they are soon up to their knees in mire, and not a dry spot to lay on. In this situation there must be much corn wasted, and they cannot possibly thrive but very slowly. My practice has been to make two square pens adjoining; they are both floored with rails, and one of them is so covered as to turn the rain, and is well littered with leaves or straw, and fresh litter added at least once a week. In the other pen a trough is placed in which they are fed from twice to three times a day. One meal they are fed of peas, and the other two on corn; it is sometimes boiled and well salted, and at other times raw. This has been my practice for three winters and my hogs have always fattened very fast and at much less than those fed in the uncomfortable manner above described.

Last winter, after killing off half of my fattening hogs, the others were fed altogether of fine corn meal, and although the weather had got much more severe, they fattened much faster than they had done before, and ate still less.

Last winter, when my fields were cut, I commenced feeding my little stock of out hogs on corn; their allowance was six quarts; but when the weather became severe, they fell away far on this allowance. I then laid the corn aside and had four quarts of corn meal boiled every day, in ten gallons of water, until it boiled down to about eight; in this half a pint of salt was occasionally thrown while boiling when done it was taken up into a large tub, and given them the next day, and in one week from the day this practice was adopted, they looked much better, and from that time increased in flesh. When the spring opened, they were fed only three times a week, in the same manner and in the month of May, reduced to twice a week, and by the middle of June it was discontinued. Had I persisted in giving them six quarts of raw corn, I am satisfied more than half would not have seen the spring.

I have also adopted the practice of grinding all my horse corn in fine meal, and find that save a third after paying the toll.

J. D. GALLARD.

From Memoirs of the New York Board of Agriculture ON THE MANAGEMENT OF SHEEP.

By the President of the Agricultural Society of Steuben County.

I am very much pleased with the prospect of another agricultural volume, and wish to contribute to it whatever lies in my power. Having turned my attention, for a few years past to the raising of sheep, I think my experience has enabled me to make some observations, which may be of service to my brother farmers.

There are two subjects, connected with the raising of sheep, to which I beg leave to direct

er attention. The one is, the most proper of the year to turn the bucks into the flock—the other is, the shearing of lambs. On former subject my practice differs from most others. I am an advocate for raising early lambs. The practice of keeping the bucks till the fore part of November, I believe injurious, and one cause why so many flocks degenerate. It is unnatural. Providence has pointed out the best season for animals to breed; that time the females are in season, and I do not believe we shall gain any thing by altering the course of nature. We suffer every individual to take its own course. My arguments in favor of the practice of suffering the bucks to lie with the flock during the whole year, are the following:—When the bucks are put into a flock late in the season, so many are in season at the same time, that the spring are feeble. The cold winds and frequent storms of the spring, together with the cruelty of keeping sheep confined at that time of the year, I have found more destructive to them than the cold nights of winter. It is also more difficult to keep late lambs over the next winter. Early lambs are also apt to have lambs the first year. My practice is to keep sheep sheltered from rain by open sheds, and shut up sheep and lambs about one week in a warm stable; and when they are a month old, they eat hay with the flock. But the sheep must be continually kept up with corn and succulent vegetables, or they will neither give milk for their lambs, or bear fine wool. There is one more benefit which arises from the practice of raising early lambs, which is, the opportunity it gives for shearing them in the summer.

I have had two years' experience in that practice, and am much pleased with it. My wool averaged, when washed perfectly clean, twenty ounces to the lamb, and sold for fifty cents a pound. The fleeces of the yearlings, having been well washed on the sheep's back, averaged about two pounds and a half. The wool was the best I ever sheared. It was of the first staple, but even, and exceedingly fine and soft. It is well known to growers of fine wool, that the fleeces of yearling sheep are not good, because the outer ends of the wool are coarse and dead. Hence it is necessary to clip such fleeces, before they can be manufactured into cloth. This evil is wholly remedied by shearing the lambs.

The time for shearing lambs is generally supposed to be about the first of August; but if lambs are allowed to fall in the winter, I think it almost a month too late. They ought to be sheared as early as possible, that the succeeding fleece, may have more time to grow. That the lamb may be eased of his "cumulous load," before the hot weather is in a measure past.

I submit these remarks with diffidence, as I am not much accustomed to writing; and especially as my ideas, in one particular, differ from those of most of my brethren in the profession.

From the same.

ON THE MANAGEMENT OF COWS.

By RUSSELL WOODWARD, of Suffolk.

Having formerly kept a large number of cows, I observed many amongst them that dried

up their milk so early in the fall, that they were not profitable, while others, with the same keeping, gave milk in plenty until late in the season. I likewise have often heard my neighbors observe, that some of their cows, though very good in the fore part of the season, dried up of their milk so early, that they were unprofitable, and they should have to put them off; accordingly found it expedient to find out the cause, if possible; and when I brought to mind the ways that some of my young cows had been kept and milked, I attributed the cause to the milking of them the first season they gave milk; and by many experiments since, I have found that young cows, the first year they give milk, may be made, with careful milking and good keeping, to give milk almost any length of time required, say from the first of May to the first of February following, and will give milk late always after, with careful milking. But if they are left to dry up of their milk early in the fall, they will be sure to dry up of their milk each succeeding year, if they have a calf near the same season of the year; and nothing but extraordinary keeping will prevent it, and that but for a short time. I have had them dried up of their milk in August, and could not by any means make them give milk much past that time in any succeeding year. In 1820, I had two heifers, which had calves in April, and after getting them gentle, I set a boy to milk them for the season, (which is often done the first season, on account of their having small teats;) he was careless, and dried them both off in August. Although I felt satisfied I should lose the greater part of the profit of them afterwards, yet I took it upon me the following year to milk them myself, and give them good feed, but to no purpose. I could not make them give milk much past the time they dried the year before. I have two cows now that were milked the first year they had calves, until near the time of their calving again, and have continued to give milk as late ever since, if we will milk them.

From the Boston Recorder.

LIGHTNING RODS.

MR. WILLIS—I see in the Recorder frequent accounts of damage done to buildings, and lives lost, by lightning; and also frequent recommendations to the people to secure their buildings by proper conductors. All this is very well; but people will never be persuaded to erect Lightning Rods, till they are in some measure convinced of their utility. The popular opinion is, that a conductor for lightning, instead of security against, only serves to invite the bolt; and that there are more buildings injured by lightning that have conductors, than there are that have not, in proportion to the whole; and this opinion is probably not altogether ill founded.

I have for several years been in the habit of examining all the conductors I conveniently could, and I find the greater part of them very deficient in one way or another.

The greatest deficiency I have noticed is in the want of a free communication with moist earth. When a rod is in all other respects perfect, and deficient in this, so far from being a safeguard, it only increases the danger it was intended to avert.

I have known, and by good authority have heard of several buildings, having conductors, but which did hardly touch the earth, being damaged by lightning. Among the many is the meeting house in Reading, Mass. In the course of the present summer the lightning came down the rod, and went off near the bottom into, and damaged the house. This was undoubtedly because, by reason of the rod not going more than two inches into the ground, the electrical fluid could not pass off as fast as it was received, and the rod became overcharged.

Lightning rods are generally made and put up by persons wholly unacquainted with the principles of electricity, and what is necessary to constitute a safe conductor.

I shall, therefore, endeavor to give some directions for the information of those who are unacquainted with the subject, and who have not the means of information.

The rod should be made of round, smooth iron, at least three quarters of an inch in diameter, and when it can conveniently be done, instead of linking, should be smoothly welded together; but when by reason of its length or otherwise it is inconvenient to weld the whole rod, let it be smoothly connected, by screwing the end of one part into the end of another. There should be five or more points, one in the centre, perpendicular, and the other oblique. They should be filed to a sharp, slender point, and tipped with silver. The points should be elevated at least five or six feet above the highest part of the building. The bottom of the rod should go into the earth six or seven feet, and terminate in a bed of two or three bushels of wet charcoal. The wet coal covered with earth will probably retain dampness longer than any other substance.

A conductor constructed and put up agreeably to the above directions, will perfectly secure a building for twenty feet on every side. When a building is more than forty feet long, for perfect security, there should be two or more rods, calculating one rod for every forty feet.

The whole expense of one rod for a two story building, including the silversing the points will not exceed \$50.

From the National Intelligencer.

ELDER.

[Sanbucus, Linn.]

The virtues of this shrub, which is found in abundance in our fields, and is now in full bloom, are not sufficiently known among us. In continental Europe it is valued and is used with success in many diseases. Chaptal, Parmenier and others, in their admirable Dictionary of natural history, applied to the arts and to domestic economy, say, that from Hippocrates down to the present day it has been employed in medicine, and its virtues and properties unequivocally confirmed by time and experience.

Its flowers are resolute, anodyne, and emollient. Infused and drank like tea, they provoke and establish perspiration in certain fevers, colds, and catarrhs; fried with eggs they are an agreeable purge; applied as a fomentation in cases of erysipelas, they reduce the heat and irritation, and prove excellent in all disorders of the skin. Warm and applied to the forehead

and temples they cure the megrim. They are used in vapor bath for swollen legs, particularly in the dropsy, in which disorder the berries, inner bark, and roots of this plant are used with great effect as a diuretic and purgative. From the berries a *rob* or thick juice is extracted, which is given with success in bowel complaints, and in the dysentery.

The flowers give a fine perfume to vinegar, and to wine the flavor of muscat; apples, when laid on a bed of these flowers when dried, and then confined from the air, acquire an exquisite taste. A decoction of its berries dyes linen when passed through alum water, of a green brown color; and excellent brandy can be distilled from them. An English farmer in the county of Devonshire, in a season when the whole of the vegetation in his neighborhood had been destroyed by caterpillars, grasshoppers, and other insects, observed that the Elder remained untouched in full health and vigor; this induced him to make an experiment which was attended with perfect success. With boughs of the Elder tied together he went over his grounds, whipping and brushing gently his cabbage plants, turnips, and even wheat, which drove off all the insects, and they never returned. He then tried the same operation on his fruit trees with equal effect. Since this discovery has been made known, some boil the branches and leaves of this plant in water, and then sprinkle this decoction over young plants, which is said to preserve them effectually from destruction by insects. A particular account of this experiment was communicated many years ago to the Royal Society, by Christopher Gullet.

The leaves and flowers of this plant when sprinkled with molasses and laid in places infested by cockroaches and ants, will drive them off.

PRO BONO PUBLICO.

As the season has now arrived for retting Flax, I thought the most modern mode of water or pond retting, would be acceptable to some of thy readers.

Having formed a pond or vat, of the size suited to the crop raised, let the flax be placed therein in bundles, with sufficient water to cover the whole three or four inches. On the flax lay some refuse boards, which are to be covered with sods, so as to exclude the sun and air. Should the weather prove warm, in four days it will be found retted, which is readily ascertained by drying a few stalks and trying them in the usual manner. Should it not prove sufficiently retted, it must be tried daily until it be so found, which seldom exceeds the fifth day unless the water is extremely cold in which it is immersed. When it is in a proper state, remove the sods and boards and take your bundles to a new mown sward and spread them, and when perfectly dry, house it and it is ready for breaking. In forming the pond or vat, care must be taken to prevent the escape of the water therefrom and to exclude the entrance of any, after the retting has commenced.

This mode has several advantages over dew retting. 1. Expedition. 2. No danger of losing the crop. 3. It will yield 10 to 15 per cent. more flax, and will sell for one cent per pound more at market, and likewise the facilities in bleaching it will be considerably increased. If

several farmers would join in forming the pond or vat, the expense to each would be found trivial.

Method for preserving Peas green for winter.—Put into a kettle of hot water any quantity of fresh shelled green Peas; and after just letting them boil up, pour them into a colander. When the liquor has drained off, pour them into a large thick cloth, cover them with another, make them quite dry, and set them once or twice in a coal oven to harden a little, after which, put them into paper bags, and hang them up in the kitchen for use. To prepare them when wanted, they are to be first soaked well for an hour or more, and then put into warm water and boiled with a little butter.

NEW ENGLAND FARMER.

SATURDAY, OCTOBER 4, 1823.

REMARKS

On the Frothing or Foaming of Horses at the Mouth, in the fall of the year, called "*Salivation of Horses*," "*Salivary Defluxions of Horses*," or "*Slavers of Horses*."

[Concluded from page 70.]

Mr. Abraham Perlee, whose communication on the subject of this article, was adverted to in our last, gives the following account of the plant, which he supposes to be the cause of *Salivary Defluxions in Horses*. "There are three species of Euphorbia common in our fields: the *maculata*, *cansicensis*, and *corolata*, of Linnaeus. There are more species of euphorbia natives, and some *exotic species* now flourish in our country, but their peculiar habits confine them to certain districts. Of the three species above mentioned, either would probably cause salivation if masticated: but the peculiarities of the *maculata* [spotted kind] render it the only one likely to be eaten by horses. None of them will be eaten if not situated or presented, as to be taken into the animal's mouth along with some agreeable grass, as clover. The *corolata* is a large plant, towering above the grasses, and therefore easily avoided. The *cansicensis* is an humble plant, attaching itself close to the ground without elevating any of its branches; and seldom flourishing among the grasses, but generally confined to open grounds, or cornfields, road-sides, &c. on these accounts it is seldom eaten. The *maculata* delighting in the well cultivated clover ground, and when closely surrounded by the clover, attaining to about the same height, and sending off many slender spreading branches, is very likely to be taken in with the clover by the larger mouthed animals. It comes forward, flowers and ripens its seed about the same time with the second crop of clover. And as clover seed is generally gathered from the second crop, it must be very liable to have some of the *euphorbia maculata* gathered with it, if any of it had grown among the clover; and in this way may be extensively diffused through the country.

"As but few of the grasses, except timothy, were propagated by seed to any considerable extent in this country before the introduction of clover, and as the low flat grounds on which timothy grows, and the close soil it forms about its roots are unfavorable to the *euphorbia maculata*, it is not singular, that, before the cultivation of clover, it should have been confined to the margin of fields and open uncultivated grounds, its native place. As this plant is not furnished with any of those astonishingly curious apparatus for dispersing its seeds that many are, and not eaten by any animal except by accident, it has not the advantages of any

means of emigrating from its native location, previous to its connexion with its friendly associate, clover.

"All the plants of the genus euphorbia contain an extremely acrid juice;—many of them stand at the head of the catalogue of vegetable poisons, many of them, when rubbed on the skin will produce excoriation; and the least acid, when taken into the mouth act as powerful masticatories. The euphorbia *maculata* possesses its greatest acrimony when in flower, a little before; and at that time the salivation has been observed to be most prevalent. Most plants when the sun is hot and the air is dry, lose much of their virtue. This is also the case with the euphorbia *maculata*, for the reason may containing it, thoroughly dried in the sun will not be nearly so productive of salivation, as when it has been slowly dried in cloudy weather. This circumstance it is worth attending to in gathering it, containing it."

Mr. Perlee observed that horses and hogs were the only animals, which he had taken notice of that were subject to salivation. But the Editor of the Memoirs of the Philadelphia Agricultural Society says, "several members of the Society have remarked cattle, sheep and swine as well as horses, to be affected by the seed and crop of clover as well as other grasses." Mr. Perlee thinks that there are other plants besides the euphorbia that will act as masticatories, but believes there are but few of them flourishing in our fields, which are able to be eaten by animals feeding on grass; and of serves in conclusion, "I am perfectly satisfied that the euphorbia *maculata* will produce it; and I have a way observed it to abound in the fields where pyramism was prevalent."

Dr. William Baldwin, of Wilmington, Delaware, is a letter to the author of the above extracts, published in the Memoirs of the Philadelphia Agricultural Society, vol. ii, p. 336, says, "a memoir was read a few years ago, before the Linnean Society of Philadelphia on the pythias of horses, in which the author states the Euphorbia *maculata* to be the cause," but observes that he had not seen the memoir; and adds, "Dr. Barton informed me that he believed several vegetables had a similar effect with the E. *maculata* in producing the *slubbers*; and that he had known this dangerous disease to be produced by dry clover, which he supposed to be in a diseased state."

There are a great many species of Euphorbia. Linnaeus made, we believe, 150 different sorts, and Wildenow no less than 300. Probably they may not all be found in America, and perhaps we may have some kinds which are not known to the botanists of Europe. As it is the spotted kind, however, to which the mischief in this case is attributed, we shall give such descriptions of that plant as we find in botanical works of acknowledged authority.

"**EUPHORBIA MACULATA. L. Spotted Spurge.**

Leaves serrate, oblong, hairy; flowers axillary, solitary; branches spreading.

"A flat plant. Stems spreading close to the ground. Leaves oblong, obtuse, obscurely serrulate on the upper part, edged with hairs, and frequently with a dark spot in the centre. Flowers very small, capsule hairy. Found in sandy soils. June, July. Annual."—*Bigelow's Florida Bostoniensis*, p. 115.

"The leaves are oblong, toothed, spotted and hairy the flowers stand singly in their bosoms.

"This is an annual, native of North America; a low plant which scarcely rises from the ground, but grows about five or six inches long. The stalk is brown; the leaves are of a dusky color, with white hairs and black spots; the flowers are yellowish."—*Hills' Vegetable System*, vol. x, p. 579.

If our conjectures are right respecting the cause of the slavers, the remedy is obvious. Exterminate the weed by tillage, and be careful not to intro-

it in your grass seed, or any other seed which you use in your course of crops. Some excellent observations on the "evil of sowing a mixture of impure with grain or grass seed," by O. Fiske, Esq. may be seen in our first volume, p. 222. We would add following from "Notices to a Young Farmer," a able tract by Judge Peters, of Pennsylvania.

Be careful to eradicate all *poisonous plants*, in pastures and fields. You will find in books, what want in experience, proofs of the necessity of this caution; and you will learn the dangers to which they are liable in this regard. Some plants are poisons to some beasts; though safe and salutary to us. A reasonable knowledge of the useful parts of any, without burdening yourself with its endless nomenclature; would enable you to distinguish plants by their properties. A *packet Magnifying Glass* (always be at hand; as not only highly useful in distinguishing plants and the enemies infesting them; but you could examine the particles composing them; and ascertain their qualities and uses. This I afford entertainment, whilst it promoted your interests. Nothing is more necessary in the inspection of whether of grain or grasses: You can discover, your glass, unsoundness or malady in the one; and of weeds and injurious seeds in the other. No person should trust the naked eye, when purchasing grass seeds particularly; wherein poisonous or noxious seeds are frequently mixed; and many are apt, as to be invisible to unassisted sight."

From the American Farmer.

SALIVATION OF HORSES.

SKINNER, having seen in your paper of the 6th instant some remarks on the salivation of horses, it put me in mind of a young Irishman who resides in this neighborhood, who said that parsley seeds were sown with clover seeds, horses would not be liable to salivation. The experiment is worth the trial, as no expense would be incurred thereby. I only recollect that 4 years ago, I saw a publication recommending wing parsley as a pasture for sheep, the writer having cured his flock of the pest by its use.

Yours, &c.

A friend to Agricultural Improvement.
Rich, Aug. 15, 1823.

FOREIGN.

last accounts from England are to the evening of the 27th August. They are disastrous to the Spaniards, and indicate that the Spaniards had nearly succeeded in opposing the will of their invaders. Corunna, according to one report, was suffering on the 16th of the horrors of a severe bombardment, and the place was on fire in several places. Another rumor is that Corunna and Algeiras had both capitulated on the 14th of August. It was asserted and believed at Paris that an arrangement between the Duke of Angoulême and the Cortes was nearly concluded, and that the defection of Ballasteros is confirmed, and that he has fled from his command. Many, and one to other officers of note have deserted to the French. Mina, however, remained firm, and said he would sooner set fire to all the towns in Spain than surrender. Sir R. Wilson escaped from Vigo, and fled to the north, where he was refused permission to land. The mission of Zayas is talked of. The French regent, Don Carlos, and the Duke of Angoulême are said to be in the hands of the Regency endeavored to procure of the Regency a modification of his decree against their imprisonment of the Constitutionalists. But the decree was in execution, and upwards of 600 men released in prison at Madrid.

Greeks are prosperous. Letters have been received from Marseilles, stating that the whole of the Greek fleet has been destroyed by the Greeks, with the exception of ten sail, and these escaped in a bad condition. The Greeks have also been successful beyond their hopes in Candia. By stratagem induced the Turks to make a sally in great numbers from the town, where their retreat was cut off. In 1800 Turks have lately been destroyed in that

Island. In Thessaly, Macedonia, and the Peloponessus the Greeks are also said to have been victorious.

DOMESTIC.

Blackstone Canal.—We learn that this enterprise is in prosecution with as much despatch as is consistent with giving an opportunity to all those who are inclined to patronize it to become interested in the concern. One route was surveyed some time since, and the estimates of expense reported. A second route is now under survey from the Blackstone Factory in Mendon to Providence, entirely distinct from the first, and every person owning land on this last mentioned route has signed a release to the Canal corporation of all claims for damages in consequence of the construction of the canal.

Curious Invention.—Mr. T. George, a clock maker of St. George's in the East, London, has lately invented an apparatus, which, by the sole agency of a clock, wakes the workmen and lights a candle at any desired time of night or morning. This is almost equal to a yankee patent-machine which we have heard of, "which," says the story, "when properly wound up, and set in motion, will chase a hog over a ten acre lot, catch him, and yoke and ring him, with the utmost neatness, precision and celerity."

Mineral Spring.—The Connecticut Mirror informs that a mineral spring of highly medicinal virtue, and as one account says, combining all the properties of the different springs in the State, has lately been discovered near Sag Harbor, L. I. Its waters possess all the qualities of yeast in making bread, causing it to be uncommonly light and spongy. Of course the spring contains a great quantity of fixed air, or carbonic acid gas.

Manufacturing Companies in New York.—There are in the State of New York, 296 incorporated Manufacturing Companies, the aggregate of whose capital is \$20,330,509. Of these 62 are for manufacturing cotton and woollen goods, 36 for cotton goods, 12 for cotton, woollen and linen cloths, and 10 for glass.

Rheumatism.—We are requested to state that the following is an effectual recipe for the cure of rheumatism:—Take cucumbers when full grown and put them into a pot with a little salt; then put the pot over a slow fire, where it should remain for about an hour, then take the cucumbers and press them, the juice of which must be put into bottles corked up tight and placed in the cellar and remain for about a week; then wet a flannel rag with the liquid and apply it to the part afflicted.—N. Y. Spec.

FRUIT & ORNAMENTAL TREES

FOR sale, as usual, at the KENRICK PLACE, near Brighton. The Nurseries have been much enlarged, and contain a variety of Pears, Apples, Cherries, Plums, Apricots, &c.—Also, the finest Nursery of budded Peach-Trees known in America; consisting of a choice collection of about 30 of the most approved kinds in our best gardens, or seen in the Markets. The trees are from 5 to 8 feet high, and sold at the Nursery at the moderate price of 33-1-2 cents each.

Of good sized ornamental trees; the Flowering Horse-Chestnut; Flowering Catalpa; European Mountain-Ash; Weeping Willow; the evergreen Silver Fir, and the Larch. English Walnuts and Butternuts, both of which are justly admired for their fruit. The latter is a hardy, handsome tree, and its bark valuable in dysentery and medicine.

Current bushes of the large prolific red kind, of all sizes, by the dozen, hundred, or thousand, on moderate terms: Also the Black, White, and Champagne do. Red and White Roses; Lilacs; English Grapes; Gooseberries, &c. &c.

Orders addressed to John, or William Kenrick, and sent to the Brighton Post-office, or the Office of Mr. Samuel Dana, Broker, in Congress-street, Boston, will be duly attended to.

N. B. Trees will be packed in clay and mats, for shipping, and conveyed to Boston when ordered: but gentlemen at a distance should employ some agent to receive and pay for them.

Oct. 4.

Impurity of the air in vaults.—A vault was opened a few days since, in the neighborhood of New York, for the purpose of interring the body of a deceased child. The colored man, who descended into the tomb with the coffin, after having placed it in the proper place, overcame by the noxious air, fell down and was lifeless before he could be taken out.

A single stalk of Millet, raised at Lebanon, N. J. the present season, produced 110 tresses, containing 6,750 seeds.

Yellow fever among cattle.—The cattle on the island of Bermuda, have of late suffered much by a disease, which the physicians have denominated the *yellow fever*.

New Process in Tanning.—We have heard tanners of intelligence as well as experience, speak highly of the mode of tanning leather, advertised by Mr. Charles Monroe, of Northborough. It is said that leather may be tanned by his process, in ten or twelve days, as well as it is in the more tedious method now practised. We understand some specimens of leather, tanned in this way, will be exhibited next Wednesday.

ON A QUIET CONSCIENCE.

Close thine eyes and sleep secure;
Thy soul is safe, thy body sure;
He that guards thee, he that keeps,
Never slumbers, never sleeps.

A quiet conscience in the breast,
Has only peace, has only rest:
The music and the mirth of kings
Are out of tune, unless she sings.

Then close thine eyes in peace, and sleep secure,
No sleep so sweet as thine, no rest so sure.

From Silliman's Journal of Science and Arts.

ON THE CUTTING OF STEEL BY SOFT IRON.

Extract of a Letter to the Editor, from the Rev. Herman Dagget, principal of the Foreign Mission School at Cornwall, Conn.

CORNWALL, Feb. 3, 1823.

Dear Sir,

I take the liberty to communicate to you a fact, which has lately come to my knowledge, and which, I judge, may be of considerable use in mechanics, and perhaps in philosophy. It may not, however, be new to you.

Mr. Barnes, (a cabinet maker of this place) had occasion to repair a cross-cut saw. (a saw to be used by two persons) of a very hard plate, which would require considerable labor, in the usual way of filing. He recollected having heard that the Shakers sometimes made use of what he called a buzz, to cut iron. He therefore made a circular plate of sheet iron. (a piece of stove pipe,) fixed an axis to it, and put it in his lathe, which gave it a very powerful rotary motion. While in motion, he applied to it a common file to make it perfectly round and smooth; but the file was cut in two by it, while it received itself no impression. He then applied a piece of rock-crystal, which had the desired effect. He then brought under it, the saw-plate which, in a few minutes was neatly and completely cut through longitudinally. When he stopped the buzz, he found it had received no wear from the operation, and that he could immediately apply his fingers to it, without perceiving much sensible heat. During the operation, there appeared a band of intense fire round the buzz, continually emitting sparks with great violence. He afterwards marked the saw, for teeth, and in a short time cut them out, by the same means. It seemed evident, that the buzz, in effecting the division never came in actual contact with the plate. Was this fire the electric fluid? If so, might it not be obtained, in greater quantity, and be made more effective for chemical purposes, by some such machine, than in any other way?

FEMALE BEAUTY AND ORNAMENTS.

The Ladies in Japan gild their teeth; and those of the Indies paint them red. The blackest teeth are esteemed the most beautiful in Guzurat, and in some parts of America. In Greenland, the women color their faces with blue and yellow. However fresh the complexion of a Muscovite may be, she would think herself very ugly, if she was not plastered over with paint. The Chinese must have their feet as diminutive as those of the she goats; and, to render them thus, their youth is passed in tortures. In Ancient Persia, an aquiline nose was often thought worthy of the crown; and if there was any competition between two princes

the people generally went by this criterion of majesty. In some countries, the mothers break the noses of their children, and in others, press the head between two boards, that it may become square. The modern Persians have a strong aversion to red hair. The Turks on the contrary, are warm admirers of these disgusting locks. The Indian beauty is thickly smeared with bear's fat. But the female Hottentot receives from the hand of her lover, not silks, or wreaths of flowers, but warm intestines and reeking tripe, to dress herself with enviable ornaments.

In China, small eyes are liked; and the girls are continually plucking their eye brows, that they may be small and long. The Turkish women dip a gold brush in the tincture of a black drug, which they pass over their eye-brows. It is too visible by day, but looks shining by night. They tinge their nails with a rose color.

An ornament for the nose appears to us perfectly unnecessary. The Peruvians, however, think otherwise; and they hang on it a weighty ring, the thickness of which is proportioned by the ranks of their husbands. The custom of boring it, as our ladies do their ears, is very common in several nations. Through the perforation are hung various materials; such as green crystal, gold, stones, a single and sometimes a great number of gold rings. This is rather troublesome to them in blowing their noses; and the fact is, some have informed us, that the Indian ladies never perform this very useful operation.

The female head-dress is carried in some countries, to singular extravagance. The Chinese fair carries on her head the figure of a certain bird; this bird is composed of copper or of gold, according to the quality of the person; the wings spread out, fall over the front of the head-dress, and conceal the temples. The tail long and open forms a beautiful tuft of feathers. The beak covers the top of the nose; the neck is fastened to the body of the artificial animal by a spring, that it may the more freely play, and tremble at the slightest motion.

The extravagance of the Myanese is far more ridiculous than the above; they carry on their heads a slight board, rather longer than a foot, and about six inches broad; with this they cover their hair, and seal it with wax. They cannot lie down nor lean, without keeping the neck very straight; and, the country being very woody, it is not uncommon to find them with their hair-dress entangled in the trees. Whenever they comb their hair, they pass an hour by the fire in melting the wax; but their combing is only performed once or twice a year.

To this curious account extracted from Duhaldée, we must join that of the inhabitants of the land of Natal; they wear caps or bonnets, from six to ten inches high, composed of the fat of oxen; they then gradually anoint the head with a purer grease, which, mixing with the hair, fastens these bonnets for their lives.

From the Washington County Post.

Anecdote of a Young Indian.—An English gentleman and his friends, travelling through a piece of woods, in one of the western states, took with him an Indian lad as a guide. In the course of the day, they separated; and one of them finding some curious berries, sent them to his companion by the lad with a note specifying

their number. The one who received the present, found some of the berries missing, and having reprimanded the boy for eating or losing them, sent him back for more. The gentleman forwarded a second parcel, with the number again marked on the note. The boy played the same trick with these, delivering only part of what he received. This procured him a second scolding. Whereupon the Indian, down upon his knees, and kissed the paper, saying, I found out, the first time, that this parcel was a witch or conjuror; but now he has proved his power to be supernatural, indeed; cause he tells that which he did not see; when I flung away these last berries, for sake of experiment, I took care to slip the order a stone that it might not know what passing.

The following handsome compliment to institutions of our country is from Bell's (London) Weekly Messenger.

"We earnestly hope to live to see the time when the European continent will become free as the United States of America are at present instant. Thinking and speaking as Englishmen, it is amazing to us, that the commerce of the continental nations should so remain the dupe of the ignorance and absurdity of the feudal systems; and should have imagined, and still continue to imagine, that such does and such institutions, such a mob of nobility, and such swarms of privileged classes, counts, such princes, such diets, and such chancellors and courts, in an infinite number, should be necessary to manage the concerns of nations, or should be enabled to manage them better wiser, than councils and presidents select more immediately among ourselves.

"The mischief of this folly, as we have had occasion to say, is not that it promotes occasions any actual tyranny, but that by means of taxation it takes two parts out of three of every man's subsistence, and impoverishes whole nations for the benefit of the few. Almost the whole police service in America is performed by an unpaid militia, instead of having those vast standing armies, which Austria, Prussia, and Russia are compelled to keep up in order to control the people. Who can rely upon the recent events in Portugal, for example, without the most painful feeling? The ancient despotism, fully triumphant. Again say, we hope to see these things at an end."

Profitable Mice.—A person in Scotland is thought to have invented a small machine for spinning thread, which is kept in motion by a rotating wire cage, in which one or two mice are kept and cause the gyrations. One person states profits on two mice at 5d. per day; and another proposes to have an establishment in which 10,000 mice shall be employed. The little animal, in the labor or amusement of a day, in a Tread Mill, travels about ten miles and a half, so much profit can be made in this way. Mice, how much more could be made from them and Squirrels?

FACTS AND OBSERVATIONS RELATING TO AGRICULTURE & DOMESTIC ECONOMY.

[BY THE EDITOR.]

CALVES.

To make calves lie quiet; more especially during a temporary scarcity of Milk; which will sometimes take place.

In this case balls made of wheat flour, and a sufficient quantity of gin to form it into a paste, given them; three balls about the size of nuts being given about a quarter of an hour after each meal. The effect is, that instead of bawling, they lie quiet; sleeping a principal part of their time.

By a little custom, the calves get fond of paste balls; eating them freely out of the manger; a proof of their being acceptable to their masters. As an expedient, they are evidently of use; and may be of service to a restless calf even when milk is plentiful.—*Marshall's New England Counties*, vol. i, p. 350.

Perhaps balls of Indian or rye meal, mixed with gin, whiskey, or other cheap spirit, will answer a good purpose, if used as above described, where wheat flour could not be easily procured. We should not advise, however, to feed calves in that manner unless they are intended for the butcher; for we should be apprehensive that feeding them with such substances, would render them too delicate and unmanageable to become hardy and profitable.

CALVES SCOURING.

To powder calves with chalk and wheat meal, work into a ball with gin.—*Young's Annals*, vol. i, p. 437.

RY COWS WHICH YOU INTEND TO FATTEN.

Take an ounce of powdered alum; boil it in three quarts of milk till it turns to whey; then add a large handful of sage, and boil it in the whey till you reduce it to one quart; rub her with a little of it, and give her the rest by drink; milk her clean before you give her; and as you see need requires, repeat the same till you draw milk from her every second day; lest her udder be overcharged.—*Agricultural Dictionary*, vol. i, p. 223.

COWS FOR LABOR.

We have never heard of cows being put to work in this country, but it does not inevitably follow that the practice may not in some cases be attended with convenience if not with profit. Mr. Young asserts, that "Mr. Bakewell draw with oxen, but now draws all with cows. He finds them as handy as oxen, and as raw just as well as oxen of the same size, except them chiefly on straw till three years when they go to bull and work till nearly four years old." In Spain, likewise, we are told that cows bear their proportion of the labor in the field. These hints may be of use to some of our new settlements, or those who live on farms, and wish to make the most of a stock.

CHOICE OF COWS.

Much depends on the choice of cows, and the care taken to mend their breed and increase their milk. Cows of a red and black color are to be preferred to white. Heifers intended for breeding should not go to the bull till the fourth year. The third, fourth, and fifth calves are best to breed from.

Cows to breed from should have eight or ten white teeth in their jaw, the breast broad, the tail long, the veins of the body distinguishable, the brace of the navel large, a broad forehead, large black eyes, wide nostrils and ears.—*Bath Papers*, vol. i, p. 212.

PROPER TIME FOR CATTLE TO BREED.

The most proper age at which cattle should be allowed to become productive is a point of much importance, but which requires more experiments than have yet been instituted to fully ascertain it. Much may perhaps depend upon climate, situation, and the manner in which they have been reared and kept. Where the situation is favorable, and their food rich and good, they may be employed in this way earlier than when they have been much exposed and poorly kept.

This is supported by the observation of Mr. Marshall, that in Yorkshire, while the lands were in the state of commonage, the heifers were frequently kept from the bull till they were three years old; now, in the state of enclosure and improvement, and at the present high rents, they are frequently suffered to take bull when yearlings, bringing calves at two years old. The arguments for bringing heifers to two years old are, that they come sooner to profit, and that farmers cannot afford, at the present rate of rents, to let them run unprofitably, until they be three years old. On the other hand, the argument in favor of bringing them in at three years old is, that not being stunted in their growth, they make larger and finer cows than those which are suffered to bear calves at a more early age."

ON MILK.

It may in general be remembered, that the milk which comes first from the cow when milked is much more strongly impregnated with any peculiar flavor than what comes last; and as that which is the first drawn is the thinnest and least valuable part of the milk, it may be taken away and applied to any inferior domestic use, without diminishing in any sensible degree the products of the dairy.

By thus separating the first from the last drawn milk, the quality of the butter will at all times be much improved, and the quantity hardly diminished in any sensible degree. For I have found, by experiment, that a small quantity of milk, which comes last from the cow, contains about sixteen times more cream than any equal quantity that comes the first at once milking, and that the cream is also of a much richer quality; the color of the one being of a deep orange, while that of the other is as white as paper.

No method of rearing can be so beneficial

for a dairy, as that usually practised in the Highlands of Scotland, where it is the universal custom to allow the calf to suck its mother for some time, take it away, and milk what remains in the cow's udder.—*Hunter's Geographical Essays*, vol. vi, p. 169.

ON COWS GOING DRY TOO SOON.

If at any time a good milch cow should go dry before her milk is gone, get a young calf, and put it too her, in order to preserve her milk against another year; for it is well known, if a cow goes dry one year nature will lose its power of acting in future.—*Bath Papers*, vol. 2, page 294.

TO PREVENT COWS FROM CONTRACTING BAD HABITS WHEN YOUNG.

Cows should always be treated with great gentleness, and soothed by mild usage, especially when young and ticklish, or when the paps are tender, in which case the udder ought to be fomented with warm water before milking, and touched with the greatest gentleness, otherwise the cow will be in danger of contracting bad habits, becoming stubborn and unruly, and retaining her milk ever after. A cow never gives down her milk pleasantly to the person she dreads or dislikes. The udder and paps should always be washed with clean water before milking; but care should be taken that none of that water be admitted into the milking pail.

MILCH COWS SHOULD BE WELL KEPT.

The keeping of cows in such manner as to make them give the greatest quantity of milk, and with the greatest clear profit, is an essential point of economy. Give a cow half a bushel of turnips, carrots, or other good roots per day, during the six winter months, besides her hay; and if her summer feed be such as it should be, she will give nearly double the quantity of milk she would afford if only kept during winter in the usual manner, and the milk will be richer and of better quality.

The carrots, or other roots at nineteen cents per bushel, amount to about eighteen dollars. The addition of milk, allowing it to be only three quarts a day for three hundred days, at three cents per quart, amounts to twenty-seven dollars. It should be remembered too, that when cows are thus fed with roots, they consume less hay, and are less liable to several diseases, which are usually the effects of poor keeping.—*Farmer's Assistant*.

PROFITS OF COW KEEPING.

Cows are certainly very profitable. Allowing one to give only six quarts a day for forty weeks in each year, and this is not a large allowance, her milk, at two cents per quart will amount to upwards of thirty three dollars; which is probably sufficient to purchase her, and pay for a year's keeping.—*ibid*.

Apple Jelly for preserving Sweetmeats.—Pare, quarter, and core, winter pippins, or almost any other kind of apples, and put them into a stew-

pan with water barely sufficient to cover them. When the fruit is boiled to a pap, add a quart of water, boil it half an hour longer, run it hot through a flannel bag, put it up in a jar, and keep it covered for use. A little lemon peel boiled with the apples, and a pound of powdered loaf sugar added to each pint of the pulp and boiled up, will make a very good apple jelly for the table, or to eat with cream.

From the Concord Observer of the 4th inst.

MIDDLESEX CATTLE SHOW.

On Thursday last the Society of Middlesex Husbandmen and Manufacturers held their Anniversary in this town. The day was highly propitious and brought together a larger concourse of citizens than on any former occasion. At eleven o'clock a large procession was formed and proceeded to the meeting house, where prayers were offered by Rev. Dr. Ripley, in a manner well suited to the occasion.—An address was delivered by Josiah Adams, Esq. which displayed a correct knowledge of agriculture and manufactures, and abounded with useful hints to the practical farmer. It was a well written essay and gave great satisfaction.—The choir of singers in their performances gave a specimen of correct and good taste in singing.—The exhibition of live stock in quality and numbers exceeded that in every former year. This proves the attention of our farmers to making improvements in their breeds and we are happy to witness the lively interest they take in this subject so important and so useful to themselves and the whole community. Many animals were exhibited which would do great credit to any show in this country; and some which in the opinion of good judges, could not be rivalled. The shows of domestic manufactures and implements of husbandry was very creditable. We should have been more gratified to have witnessed a larger number. But the workmanship of the different articles exhibited did great credit to the owners, and evinces a spirit of improvement in this department, which cannot fail to be of service to the people.

The ploughing match excited a deep interest, and it was truly gratifying to witness the scene—the great number of spectators it called to the field, and the attention and order with which it was conducted, the neatness and regularity of the work, all conspired to render it a great addition to the day.

In addition to the above several neighbors in Lincoln, united and brought upon the field a very handsome team of working oxen which for excellence in their form and appearance did great credit to their respective owners. Another team was also produced by a few individuals in the southerly part of this town, composed of excellent cattle. These added much to the exhibition of the day, and gave evidence what our farmers can do, and what they can show—without any thing more than their common attention to raising good oxen.

After the several committees had performed their services, the members of the Society and others repaired to the hall of Mr. Allen and partook of an excellent dinner prepared for the occasion, after the cloth was removed the following sentiments were drunk with good cheer, viz:

1. The President of the U. States and the Governor of this Commonwealth—They both assisted in first breaking the soil of freedom, and are now reaping a rich harvest.

2. The best soil is that which has no lordlings, but permits every man to become the builder of his own family and the architect of his own fame.

3. The Union of the States—A chain too strongly welded to be broken by all the Bullies of the North, the South, the East and the West.

4. The Farmers' and Manufacturers' Holiday—A day rich in fruit and good works.

5. The plough share—A better share than that of Banks and Turnpikes.

6. The next Presidential Ploughing Match—The people are a team who will go steady to the work and will not be diverted by the buzzing of flies, the cobbles stones of interest, or the roots of intrigues.

7. The daughters of our Land—May they be stayed with domestic economy; girdled with good works; and remember that a good wife is a price far above rubies.

After dinner the members of the Society and citizens met at the Court-House, when the premiums awarded by the several committees were announced as follows, viz:

ON CATTLE.

To David Perham, of Chelmsford, for the best Bull, \$15
To do. do. do. for next best do. 8
To Daniel Clark, of Concord, for the best pair of Working Oxen, 12
To Stephen Patch, of Lincoln, for the next best, 6
To Joseph Valentine, of Hopkinton, for the best Heifer, 8
To Paul Adams, of Concord, for the next best, 4
To Stephen Patch of Lincoln, for the best Bull Calf, 4
To Nathaniel Smith, of Hopkinton, for the next best, 3
To Stephen Patch, of Lincoln, for the best Heifer Calf, 3
To Amos Davis, of Groton, for the best fatted Ox, 10
To Silas Conant, of Concord, for the next best, 7

In the competition for the second premium on fatted cattle, there were two oxen, one exhibited by Maj. James Barrett, and one by Capt. William Brown, which were fine and well fatted animals, and nearly equal to the one which obtained the premium.

To the Rev. John B. Wright, of East Sudbury, for the best milch Cow, 10
To Timothy Prescott, of Littleton, for the next best, 7

ON DOMESTIC MANUFACTURES.

To Benjamin Wheeler & Co. of Framingham, for the best piece of Broadcloth, 3
To Rock Bottom Manufacturing Company, for Casimere, 3
To George M. Barrett, of Concord, for the best piece plain Cloth, 3
To S. H. Rockwood, of Groton, for the next best, 6
To Mrs. Sarah Rogers, of Tewksbury, for the best Carpeting, 4
To Ephraim Coburn, of Dracut, for the next best, 6
To Mrs. Ann Benis, of Watertown, for the best Hearth Rug, 2
To Misses Mary and Betsey Munroe, of Lincoln, for 2 Hearth Rugs, 2
To Joel Whitcomb, of Roxboro', for the best Woolen Coverlet, 3
To Ezekiel Byam, of Chelmsford, for the next best, 2
To Mrs. Meriam, of Concord, for 3 pair Half Hose, 2
To Miss Lydia Hosmer, of Concord, for one pair Woolen Blankets, 2
To Ephraim Coburn, of Dracut, for the best piece Linen Diaper, 2
To Miss Betsey Benjamin, of Concord, for the next best, 2

ON LEATHER.

To John Vose, of Concord, for the best Sole Leather, 4

To Isaac Hobbs, of Weston, for the best Calf Skins,

ON BOOTS AND SHOES.

To Abel Moore, of Concord, for the best pair Boots, for the best Men's Shoes, for the best pair Women's do.

ON HOGSHEADS.

To John Pushee, of Littleton, for the best Hogsheads, To Daniel McClenning, of Littleton, for the next best,

ON LEGHORN AND STRAW BONNETS.

To Miss Meriam R. Haven, of Hopkinton, for the best Straw Bonnet, To Miss Dalrymple, of Marlboro', for the next best, To Miss Olivia Stanley, for an elegant Lace Bonnet, ingeniously trimmed with straw, To Miss Meriam R. Haven, for a curiously wrought Straw Calash,

ON INVENTIONS, IMPROVEMENTS, &c.

To Miss Hannah Fletcher, of Chelmsford, for an Indispensable made of native grass, 1
To John Thoreau & Co. of Concord, for a specimen of excellent Lead Pencils, Manufactured from American Plumbago, 1
To Robert Chaffin, Jr. of Acton, for a cooper's Howell, on an improved plan, 8
To Alvan Pratt, of Concord, for a double barrel Rifle Gun of great ingenuity & superior workmanship, 12
To Col. Daniel Brooks, for a specimen of Carolina Potatoes raised by him, 8
To Tilley Merrick, of Concord, for another specimen, 4
To Comfort Foster & Co. for the best Hats, 4
To Mr. Danforth, for the next best, 3

MERINO SHEEP.

To Nathan Barrett, of Concord, for the best Merino Ram, 3
To George M. Barrett for the next best, 3
To George M. Barrett, for the best Merino Ewe, 3

The Committee on the Ploughing Match having attended that service, ask leave to report—

The whole number of Ploughs offered premium were six, to which, the ground prepared by the committee of arrangements, tributed by lot. Lot No. 1 was drawn by Nehemiah Flint and was performed in 27 m. 40 sec.—18 furrows 6 inches in depth. Lot 2 drawn by Josiah Haywood and not finished until the committee left the ground. Lot 3 drawn by Liab Lee, and work performed 27 min. 29 sec. 22 furrows 4 1-2 inches depth. Lot No. 4 drawn by Nathan Wright performed in 32 min. 27 sec. 22 furrows 4 inches in depth. Lot No. 5 drawn by Henry Wheeler, work performed in 35 min. 10 sec. 18 furrows 4 inches in depth. Lot No. 6 drawn by Daniel Clark, work performed in 22 min. sec.—18 furrows 5 inches in depth. The Committee after visiting the ground were unanimously of the opinion, that the first premium awarded to Mr. Daniel Clark, the second Captain Nehemiah Flint, and the third to Liab Lee. The Committee ask leave state that they were upon the whole, much gratified with the performances, that they generally did honor to those who contended the prizes. But they however beg leave recommend to those who should in future enter the list at the ploughing matches to commence with less rapidity, and to make less use of whip.

Per order

JOHN BUTTRICK, Chairman.

HARTFORD, (CON.) OCT. 7.

CATTLE SHOW.

to flatter ourselves that the approaching anniversary of the Cattle Show will attract no ordinary interest among our citizens. In a few days we hope to see this celebration take place, and the other holidays, with the exception of the day which gave birth to our Independence, solemnity and interest to the feelings no other festive days can be compared to it. Albany has it excited emulation among the farmers, the effects of which are visible in extensive improvements, not surpassed by any section of country, nor even, as we believe, by the farmers in Pennsylvania. Connecticut has for many years been distinguished for her beef and pork, the staples of our state. The laudable emulation and competition called forth by this annual exhibition of stock, is not a little calculated to maintain the ascendancy which we have over some of our neighbors in the market. These exhibitions of works of art and taste at the state-house, have uniformly called together great numbers of people than we have seen on any other occasion. All present seem highly gratified with the scene, and the entertainment with innocent and improving. It is greatly to the interest of this county, to cherish the memory of these annual meetings. The profit arising from the premiums bestowed on such exhibitions, should be deemed a trifling object in comparison with the general benefit which will result from the opportunities for imitation and improvement afforded by them. Many public spirited citizens, have, from a sense of duty, and not any private interest, been induced to go forward and subscribe liberally to encourage the Cattle Show. All the return that is asked or expected, is that those who have any objection from their farms, or of mechanical industry, should exhibit it for public inspection. Relative patronage will eventually be extended to these societies, in case the people evince the same spirit of emulation as in some of our sister states, which have appropriated liberal aid for the object. There is, by the late regulation, but one day devoted to the Cattle Show; and it will be necessary, that those who exhibit, should be early on the ground, as there will be a great loss to be lost, in order to go through the business of the day. In the county of Worcester, great exertions are using for their ensuing Cattle Show, than on any former occasion—and we are not to be outdone by this enterprising county of the state of Massachusetts. *Courant.*

and Bristol County.—The first Cattle Show of the Bristol County Agricultural Society will be held at Taunton, the 21st and 22d instant. We can say with confidence, that if the Agricultural improvements in this county, are in any proportion to its improvements in manufactures, railways, roads, and commerce, this Show will be well worth seeing; affording evidence of increased wealth, prosperity, and enterprise of this ancient county; and that though we do not exhibit, she is not least in her ability to give a Show. *Boston Centinel.*

To the Editor of the New England Farmer.
When will it be convenient to insert plates or geometrical figures? I am impatient to be publishing some of the rudiments of my new and

useful science, called Semi-Geometry, to perform arithmetical calculations by Projection, with a scale of equal parts, and a pair of dividers. I wish to show how to project the contents of a cask of cider, and a few of the principal problems, in order to induce others more in the prime of life to pursue and improve my discoveries in a science so very useful in mechanical business.

At present I may give some account of the improved mode of calculating interest. The late learned *James Ferguson* invented and published a table, showing the interest of any number of pounds from one to a million, for any given time or rate per cent. to the hundredth part of a farthing. His precepts are,

1. Multiply the sum by the number of days.
2. Multiply that product by the rate per cent. and cut off the two figures to the right hand.
3. Then enter the table, as in the following example.

What is the interest of £100 for 365 days at five per cent.?

Number of days	365
Multiply by	100
	36500
Multiply by 5 per cent.	5
	1825,00

	£	s.	d.	qr.
By the table	1000	is	2	11 9 2 11
against	800		2	3 10 11
	20		1	1 60
	5		3	1 15

1825 £5 00 0 00 Inter. req.

And the same rule and tables show the true interest for any number of pounds or days. I calculated a continuance of his tables to include *shillings and pence*.

As the United States' currency is dollars and cents, Ferguson's tables would not answer; and as there is but nine numbers in nature, and any thing more or less is repetition to the left hand or right. I invented and calculated *nine proportional logarithms* that will show the interest of any sum from one cent to a million of dollars, for any rate of days or rate per cent. to the thousandth part of a cent, to be wrought by the same precepts as Ferguson's tables. To illustrate this I give the following example.

What is the interest of \$200 for 365 days at 7 per cent.?

Number of days	365
Multiply by \$200	200
	73000
Multiply by 7 per cent.	7
	5110,00
By the table,	\$ c.
Against	5000 is 13,69,8630
	100 27,3973
	10 2,7397
	14,00,000

The whole of these logarithms and precepts could be printed on one page of a pocket almanack. *SAMUEL PRESTON.*

Stockport, Pa. Sept. 13, 1823.

We are ever happy to receive communications from Mr. Preston relating to any subject, which may come within the professed object of our paper. But we apprehend some difficulty in giving correct plates to illustrate his "new and useful science called Semi-Geometry," unless the author, or some other person, conversant with the subject, should be present to give directions to the artist while engraving the plates, and to inspect the press while the work was printing. Besides, our patronage is not at present sufficient to enable us to give numerous and expensive engravings. We hope these objections may be obviated, and in such case we should be glad to be instrumental in making public any of Mr. Preston's discoveries, calculations, or elucidations of "Semi-Geometry," or any other useful art or science. In the mean time, we hope he will continue to present us with such observations as his good sense, combined with much experience and observation shall suggest, as worthy of his own reputation, and beneficial to the community.

A new and valuable discovery for the curing of Beef and Pork Hams.

Pyroligneous acid or essence of smoke. This essence contains all the properties which are necessary for the curing of beef and pork hams without the common method of smoking; and is not attended with half the expense as is requisite in the usual manner of making bacon. We do not give a description of this essence to raise its merit or deceive the public, but simply to mention some of its qualities, which can be known only by applying its antiseptic virtues to the curing of beef and pork hams and preserving fresh meat a longer time from detriment, from flies and hot weather.

One quart of this essence will cure two hundred pounds of hams put down close in a barrel, with salt and water sufficiently strong to bear up an egg. Put one ounce of pulverized salt petre and a handful of salt to each fresh ham and half a pound of brown sugar or molasses in proportion.—Put one quart of essence into the barrel with the hams and pickle, let them remain three weeks, and hang them up to dry. If you choose, you can let them remain in the pickle till wanted for use, which will preserve them from shrinkage, flies, or any other detriment. Those who prefer the ordinary pickle may add one quart of the essence to the barrel. Hams cured in this manner, retain all the flavor of the best hams smoked in the usual way.—*Brooklyn Observer.*

Grand Canal.—The London papers notice the progress of the Grand Canal of this state, in terms highly flattering to our citizens. After remarking that it is the longest canal in existence, measuring 353 miles in length, and that its cost, when finished, would be about five millions of dollars, the British Traveller says, "It is a work worth a thousand Escurials and Versailles, because it creates wealth, while these only consume it: and it is a monument of public spirit and national prosperity, while these are only monuments of idle magnificence, vain glory, and despotic oppression. When shall we see the inhabitants of a small province of any of the torpid and priest-ridden monarchies of continental Europe execute such a work by their own spontaneous act, and with their unassisted resources?"—*N. Y. Evening Post.*

From the Amherst Cabinet.

CATTLE SHOW, &c.

On Wednesday and Thursday last the Hillsborough Agricultural Society held its annual Cattle Show and Fair at Francistown. The large concourse of people which assembled on the occasion manifested the deep and increasing interest which they feel in these exhibitions. There were even those present who have been loud in decrying them as useless.

On the first day, the pens appropriated for the cattle were early filled with rare specimens of improved breeds in all the branches of competition for which premiums were offered by the Society. The stock in general was excellent in kind, and if not superior to that exhibited last year, yet was such as to do honor to the occasion, and credit to our farmers for their continued enterprise and exertions to improve their stock. The exhibition of Domestic Manufactures was also a handsome display of the ingenuity and persevering industry of our yeomanry, their faithful wives and worthy daughters; being chiefly specimens of household industry, comprising many articles of excellent fabric. And of the Butter and the Cheese, every one had the indubitable evidence of gustation, and if we can judge any thing from the gesticulations of the participators and the quantity consumed, they were both good. Of these things, however, a more minute account will be given hereafter.

On Wednesday, after the usual preparatory measures, the awarding committees proceeded to examine the stock and manufactures, and to make up the reports of their decision to be laid before the Society. At 5 o'clock the Society met for the choice of officers for the ensuing year, and other business of the annual meeting. After discussing the measures proposed, and appointing committees to report thereon, an adjournment took place to eight o'clock next morning, when the business was completed. At 11 o'clock the Society formed in procession, and proceeded to the ground appropriated for the Plough Match. Thirteen yoke of Oxen were entered for this interesting competition. The scene was a very animating one, and thousands testified their deep interest in it, and expressed their joy by loud and reiterated acclamations. A description of this match and the trial of strength of the oxen in drawing a dead weight on the drag, will be given by the appropriate committee. After the ploughing match, the Society returned in procession to the arena formed by the square of pens, where a table was covered with the premium butter & cheese, a plenty of good bread, made of the finest of the wheat that grows on our hills, and the best of old orchard, on which they fared sumptuously. Here they were honored with the company, as guests, of His Excellency the Governor, with a great concourse of ladies, whose beauty, smiles and appearance added brilliancy and animation to the show. All together and with one accord demonstrated that they were lovers of bread and cheese and one another. After dinner the Society repaired to the meeting-house, where an appropriate discourse was delivered by the President, the Reports of the awarding committees presented and read, and the premiums paid to the successful competitors.

From the American Farmer.

BOTTS IN HORSES.

DEAR SIR,

I have read in the American Farmer, of the 15th instant, a communication on the subject of botts in the stomach of horses, addressed "to Mr. Lunday," referring to an extract from a Lexington paper, purporting to be an effectual remedy for the botts, (that prescription I have not seen, having mislaid that number,) signed "A Subscriber"—I have made similar attempts to destroy them, after dissecting the maw or stomach of horses which have been killed by botts, but have discovered nothing will kill the botts (which I tried) that would not kill the horse, if given to destroy the botts while in the horse. I have concluded the only way to save or cure horses, when attacked by botts, is to extract or make the horse discharge them—I have found them troublesome to horses before they had eaten into, or fastened on the maw or stomach; indeed I have seen the botts collected in the throat of the horse, in such lumps or quantities, as to choke and kill the horse instantly; which will always be the case if relief is not given, by inserting into the throat a mop, or the hand of the groom to dislodge them, returning them into the stomach, when they so collect in the throat. The best and most effectual cure I have yet discovered, is to *dislodge and bring away* the botts, which I have done, by drenching the horse affected, with warm blood, say one or two quarts, or more if it can be conveniently obtained, as there is no danger in giving any quantity injuring the horse. As soon as the dose thus given, reaches the botts in the stomach, they will let go the maw or stomach to feed on the blood thus given—which gives the horse instant relief, but of short continuance if they are not speedily removed, which must be done by cathartics.—Say Linseed Oil, 1 quart, or such quantity judiciously given as will purge freely; keeping food, (except drinks, or bran tea warm) from the horse until the operation is over, during which gentle exercise is advisable, when it will be found the botts will be freely discharged in so healthy a state, that aqua-fortis will be found scarcely sufficient to kill them—I have during the month when soft corns (roasting ears) were to be had, given the horse of them to eat plentifully in preference to oil—they purge freely, and the time brings the worm away forcibly. I have often tried this remedy after all efforts were suspended, and have rarely known it fail, and never when first used, or before the bott had eaten through the stomach. I was led to the experiment of giving blood, from the reflection that it was the food of the bott, which they were in pursuit of—to obtain it I always have recourse to one or more of my healthy strong horses, as the quantity desired may be. Though I have bled in the neck, and used the blood of the horse affected, (when no other horse was convenient) without any hesitation, and I believe it will not be found injurious to bleed horses occasionally when in health, but rather beneficial to most horses.

I have known horses relieved when attacked by botts in some instances, by killing the dung-hill fowl and taking the entrails while warm and cramming them into the stomach of the horse, though I have not myself confidence in its curing or relieving, where the botts have

taken fast hold—to prevent botts, burn hickory wood into ashes and keep on hand for use, giving once a week about one pint to each horse in his food; if oats, wet and sprinkle the oats the horse will eat them without objection, and I think it, perhaps, the means of keeping horses in health, where they would, without the ashes fed, have been diseased from other causes, which your own investigation will, no doubt, inform you they are subject to.

I give you the trouble of reading this reluctantly, leaving it for gentlemen of more leisure and experience to attempt instruction or edification.

NIMROD OWINGS.

Fountain-Rock, Aug. 25, 1823.

Our distant readers are warned that they may have confidence in what they see from the pen of our correspondent above, in relation to the noble animal, the horse. Mr. O. is known to possess a stock of horses, and to be one of the best judges and masters of that useful animal in this country.—*Edit. Am. Far.*

From the Old Colony Memorial.

SIR—I am by occupation a husbandman, and have always worked hard for a living. I possess but few acres of land, endeavoring to improve it to as much advantage as possible; and on which is a beautiful apple orchard, exceedingly productive. I have also cherry, pear, peach and plum trees, which it has ever been my pleasure to cultivate, sparing no pains or labor about them. My garden too is the source of much profit, pleasure and satisfaction, producing me a great variety of fruits and roots. Watermelons and muskmelons I generally raise in great profusion; and I will venture to say no one takes more pleasure in feasting his friends and neighbors with those bounties of Providence than I do, although they are procured not without much tug, and toil, and sweat of the brow. But, notwithstanding I never deny fruit to any one, who condescends to ask for it, yet I am continually haunted and harassed by night plunderers and fruit stealers. And it has become so serious a matter that I have had thoughts sometimes of pulling up stakes, as we farmers say, though some call it a military term, and removing to some distant country, where I can be free from such molestations. Some, who are strongly suspected of joining in this disgraceful business, have the reputation of respectable young gentlemen; but, Sir, let me tell them, that he, who skulks at midnight, like a prowling wolf, through gardens and orchards, lichen and destroying what the hand of industry has labored hard both late and early to bring to perfection, is, without any qualifying epithet, a barbarian, a thief, and a robber! Yes, as much a robber as Michael Martin or Thunderbolt!

One favorite pear tree I have of inestimable value; a true St. Germain, which was loaded with fruit this season.—It was but the other day, my wife being in the garden and casting her eyes upon this beautiful tree, expressed her astonishment at its wonderful productiveness. "We must gather them carefully," said she, "that they may keep the better. Our friends in Boston must have some, and we must not forget our worthy parson, you know." "And, mamma," cried little William, "if the thieves

From the Farmer's Magazine.

ON THE NECESSITY OF CHANGING SEED.

"Have you found it of service to change the seed of plants, from one soil or climate to another, and why?"—From the most universal adoption of the practice, it seems that experience has fully justified it. In the case of exotics, that do not arrive at perfection in an alien climate, it does not seem wonderful; but in the case of naturalized vegetables, I cannot explain it."

Bath Society Papers.

Sir—Not having access to a complete set of your useful work, I am not aware of what discussions it has furnished on the subject of the necessity of a change of seed in the cultivation of corn; but, as an endeavor, however humble, to fix the principles of that necessity, may at the approaching season not be uninteresting to farmers, I have taken the liberty of submitting what has occurred to me from an imperfect consideration of it.

I understand a belief in an *abstract* necessity for an occasional change of seed, to be very generally entertained, and to be founded on a supposed repugnance between the soil of a farm and a succession of plants descended from a particular stock of seed. This antipathy is said to be a secret principle in the economy of plants; and those with whom I have conversed, unable to account for it, consider it sufficient to say, the soil tires of the plants, or the plants of the soil. In this, it appears to me, there is much delusion; for I hold that, *abstractedly*, there is no efficacy in, and therefore no necessity for, a change of seed. The grounds of this opinion I shall endeavor to explain.

Without going into the never-to-be-determined question, What is the food of plants? I take it for granted, that each species of vegetable has its peculiar pabulum; and that this peculiar matter must exist in the soil in which the seed of that plant is sown, otherwise it will not be produced in a perfect state. If any particular species of vegetable be repeatedly cultivated in the same field, it may so exhaust its food in that soil, that the latter will become unfit to produce the plant in perfection; and other circumstances, such as the application of certain manures, may incapacitate a piece of land from carrying a particular species of plant to maturity. But, in this case, a mere change of seed will not prove a remedy. Something must be done to restore to the land the pabulum of the plant sought to be cultivated in it, otherwise a change of seed will prove of no avail. Again, I conceive that a plant, after being deteriorated, by unfitness of soil, inadequacy of climate, or faulty cultivation, may be restored, by being transferred to better soil, or a more genial climate, or by being more carefully cultivated. But this is no proof of an abstract efficacy in a change of seed. Here there is a concomitant change of circumstances, which plainly accounts for the improvement: for we are entitled to hold, that corn, once degenerated, cannot be reproduced in a more vigorous state, unless it is transferred to land different in the circumstances either of climate, soil, or mode of cultivation. Still further, corn crops may degenerate by the gradual operation of an unfavorable climate, or by the natural barrenness of the soil in which they are raised. In such a case, the farmer finds an advantage in having recourse to fresh seed, the produce of a more genial climate or better land, or even of a neighboring farm under the same circumstances of soil and climate as his

own, if the corn produced on that farm, from being more nearly related to a good stock of seed, happens to be less degenerated. This, however, does not furnish evidence of an abstract efficacy in a change of seed; for it is clear, that the farmer would not have bettered his circumstances had he not obtained seed of a quality superior to what was produced on his own farm. Again, we know that crops may become deteriorated, by the adoption of the too general practice of sowing corn nearly as it grows, using little pains to separate the good seeds from weak and imperfect ones; or by many other circumstances of mismanagement. In such a case, it may be a temporary improvement to obtain a fresh supply of seed. But this does not establish the abstract efficacy of a change. In short, in every supposable case of change of seed, any improvement that takes place must be the effect of some concomitant change of obvious circumstances; and the necessity of the change seems to have no relation to the *je ne sais quoi*, that mysterious antipathy between the soil and a particular race of plants, which is said to be excited by their long familiarity. This is the abstract necessity for 'changing the seed of plants from one soil of climate to another,' unless in the case of degeneracy of crops, from some of the obvious causes I have alluded to; and in such a case, an improvement can be effected only by obtaining a supply of *better seed*. This, too, is the only case in which there can be any *efficacy* in a change, except the object be to obtain a better *variety* of a particular plant than what is already possessed. With this view, it may be justifiable to sow seed, though even inferior, *as a sample*, to what is already produced on the farm, if superiority of soil, climate or cultivation, afford a reasonable prospect of improving the *quality* of the new variety.

I am quite aware of the nicety of this question, and sensible of my own incompetency to the discussion of it; but I shall think I have done enough, if some of your enlightened correspondents should be induced, from what I have said, to edify us with their sentiments.

Stonehaven, Jan. 3, 1820.

Xx.

From the New York Advocate.

DANDY HATS.

Our city has been much amused with a low tripod-kind of a hat, made of fine beaver, and worn by our Bang-ups. Some call them the *Touche*, others the *Gape and Stare*, the real name is the *Bolingbroke*. It is about six inches in crown, and four in rim, shaped like an inverted cone. It is a real tipper. We yesterday saw one of the fancy, dressed quite unique, blue frock, black silk Wellington cravat, buff waistcoat, Cossack pantaloons, high heel boots, black ribbon and eye glass, bushy hair frizzed, and surmounted with one of these little tippy hats. He looked like an hour glass, and minced his steps along Broadway in the real Jemmy Jumps style. The ladies were highly amused, and more glasses were directed towards him, than would be to the Emperor Hurbide, had he just landed; while our blood, insensible to all this curiosity danced up the street, humming the favorite air of, "Look dear ma'am, I'm quite the thing; natus hay, tippity ho!"

to carry them off, you will send some to con-
Nancy, you know?" "Yes, child, cousin
ally shall also be remembered. The thieves
not take them now, because they are too
to be eaten, and we shall endeavor to gather
them in season." These were our fond an-
imations and pleasing hopes, but they were
disregarded by the barbarous destroyer,
the next morning I looked at my pear tree
and beheld it was as barren as the fig tree of
any! My feelings and indignation I cannot
press. The interesting scene which my wife
child in the garden but a few hours before
to my mind, and I confess I became a child
self, and sorely wept. Call it weakness, or
it you will, I care not. This pear tree is
favorite *Eclipse*. Suppose the famous horse
that name should be stolen by some Canadi-
harper, what would be the ado, the bustle,
complaining and execrations! and yet, sir,
them my pear tree of more worth than a
dozen such horses!

This evil is not confined to a single individu-
sir; it is very well known to be general
throughout the country. What then can be
done? Is there no remedy against such shame-
ful and abominable villany? And is it generally
admitted to that to rob an orchard or garden is
a crime; and that a watermelon frolic, as it is
commonly called, is but a piece of innocent
fun? Must an unfortunate debtor be harassed
and persecuted, and confined to the cells of a
prison for being unable to pay his debts, while
a midnight marauder and fruit robber by
common consent goes free and unmolested?
Does the law on this subject? It imposes
a penalty of not less than five, nor more than
ten dollars on any person, who shall enter the
possession of another without leave, with intent
to injure, &c. and take therefrom any grass, hay,
or vegetable or shrub, cultivated thereon for
food or ornament; besides a forfeiture of treble
damages. Thus we see that the legislature
has done all that is necessary; and it remains
for the good people of the Commonwealth to
execute the law in execution. I then call on the
community at large, whose interest it surely is,
to attend to this one thing needful. In every
case, where there is a discovery, suffer no vil-
lany to go unpunished. No matter who he is,
nor that he is; let him be made an example of.
Apply particularly on all, who are engaged
in agriculture, horticulture, and the culture of
the city, industry, good morals and a good neigh-
borhood to make it their business to discounte-
nance and put down this shameful and diabolical
trade. Let there be clubs and societies formed
for the prevention of these crimes, as well as
others. If it were consistent with the regula-
tions and designs of our agricultural societies to
offer premiums to those, who should detect
stealers of fruit, as well as to those who should
cultivate it, I have no doubt they might in
this way greatly promote the interest of agricul-
ture and be of still more essential benefit to
the public. Now, Sir, of him who is disposed
to call this a trifling matter, let me ask; who
will rise early and work late, and tug, and
toil, to set out and cultivate, and nurse, and
manage an orchard—to till, and toil, and plant
the field and gardens all for the sport and depre-
dations of a set of scoundrel pilferers?

Yours, &c.

JOHN LANDMARK.

A warning to thoughtless Jesters.—There is now in the New Bedlam, London, a man who was driven mad by being suddenly startled: "As he was one morning crossing his father's fields, on his way to his usual labors, cheerful and guardless, an intimate rustic acquaintance saw him coming, knew his simplicity, stepped aside, and concealed himself behind a bush until the other came up, when he suddenly rushed upon him with a loud shout. He was so astonished by the shock, that he was struck almost senseless; he staggered, fell, and fainted away. The current of his blood seemed for some time arrested, and his pulsation ceased. He was taken up and conveyed home; delirium ensued and madness followed, which has ever since continued without abatement, to a degree not only pitiable, but dangerous to all who approach him."

Floating Grist Mills.—This kind of mills is used in abundance on the river Ohio. The mill is supported by two boats, and the wheel, which is the principal part of the machinery, moves between them. The boats move in every direction on the river, and when employment can be obtained, they are generally placed near the edge of it, in the strongest current, and the mill is then set in motion. These mills will grind a bushel of corn nearly as quick as those propelled by water. It is by this means that many neighborhoods, and even towns are supplied with their corn meal.

Ogden's Letters from the West.

Wine.—A Danish chemist has demonstrated that apple juice mixed with a great quantity of sugar produces a drink which more resembles wine than any other substitute. Cherries and currants, he says, are not so proper for wine as the apple.

NEW ENGLAND FARMER.

SATURDAY, OCTOBER 11, 1823.

BRIGHTON CATTLE SHOW.

So far as we have been able to observe, appearances indicate that the exhibition at Brighton of the 15th and 16th inst. will command not merely a renovated but an increased interest. Expectation is broad awake, and Attention all alive to the anticipated proceedings and displays of the Husbandman's Holiday. The competitors for the Premiums, the Champions of the PLOUGHING MATCH seem eager for the friendly contest—emulous to engage in that amicable strife, in which the Cherub of Peace will twine the laurel of the Conqueror, and the shouts of the victor will not be mingled with the groans of the vanquished. The pleasures of such a day are as pure as they are exquisite; the means are amusement, the end utility; and the mind is improved by the same objects which gratify the senses.

We hope that none amongst the multitude, which it is wished and expected may assemble on this occasion, will consider themselves as lookers-on merely, who convene for no other purpose than to while away an idyl hour, and feast on the fat of the land. We hope that those who view themselves as spectators, and have no parts assigned, will not be contented with idly swelling the procession, or filling chairs at the festive board. All have something to communicate or something to learn, or both, which may help to supply the necessities, add to the comforts, or enhance the innocent enjoyments of the great family of man. We hope that social intercourse will be so correctly cultivated as to

produce not only the Flowers of Friendship, but the Fruits of Useful Knowledge; and that every minute of time spent at the Cattle Show, will leave behind it the stamp of improvement. We hope that at the close of the exhibition every individual will be able to say, "I have not only been amused but benefited by the Farmer's Festival and Artist's Anniversary." In order to induce this very desirable consummation, let every avenue of useful knowledge be opened by its possessor. In other words, let every person tell what he knows, and learn what he can, respecting the great objects of the association. Let us drink deeper at the fountains of knowledge than at the bar of the landlord. The pleasures of the anniversary will then leave no sting, but survive in agreeable reminiscences. Anticipation will not only be crowned by fruition, but consecrated by recollection; and we shall all be able to say, that a day spent at the Brighton Cattle Show is better than many spent elsewhere.

The following article was marked for insertion in our last paper, but omitted by mistake. This circumstance we regret, as we consider the PLOUGHING MATCH as the *Cap Sheaf* of a Cattle Show; and as necessary to give a *finish* to the customary proceedings on such occasions as a dessert to a feast, or a glass of cider to a farmer's dinner. Sir John Sinclair, the first agriculturist in Europe, has expressed some opinions on this subject, with which we believe every considerate cultivator will fully coincide. The passage we allude to was doubtless dictated by experience, and is so much to the purpose of the contemplated match at Brighton, that we are certain we cannot do better than to give it at full length.

Ploughing Matches.—From the great importance of good ploughing, every means should be thought of to extend a practical knowledge of the art; and no plan has been found more effectual for that purpose, than that of establishing a competition among ploughmen, and rewarding those who excel. At such meetings, farmers have been instructed, when they only came to be amused; their prejudices have worn away; and they have been induced to try new instruments of husbandry, and new modes of culture. Were it possible to impress upon the minds of our farmers in general, the great importance of good ploughing, more especially the advantage of using ploughs with two horses (or oxen) without a driver, and to make them sensible of the benefits of deep ploughing; several millions per annum would be added to the value of the united kingdom.

Among other motives for improvement in the structure and management of the plough, we would suggest one, which perhaps is not generally adverted to. "The merciful man is merciful to his beast." Our oxen and our horses should have good tools to labor with, as well as their masters. By facilitating the labors of the poor quadrupeds, who afford their all important aid to the husbandman, we obey as well the dictates of humanity as of self interest. Even the cattle of our pastures and stalls, "had they our reason," and powers of speech, would therefore manifest their approbation of PLOUGHING MATCHES.

PLOUGHING MATCH AT BRIGHTON.

The Committee of Arrangements for the Cattle Show in Brighton, have been furnished (as on several former occasions) with a suitable piece of ground for the Ploughing Match, by Mr. Francis Winship—it is north of his house, on the road leading from Cambridge to Brighton Meeting-house, a few rods from the ground used for the same purpose last year; is laid out in lots by a careful surveyor, viz:—eleven lots of one eighth of an acre each, to be ploughed

with one yoke of oxen, and nine lots of one quarter of an acre each, to be ploughed with two yoke of oxen. The soil in quality is near alike as can be expected in a level plat the requisite size, with a margin for the accommodation of spectators. The following extra is from the premium list published in January last, and distributed through the State—"At the second day of the Cattle Show, viz. the 16th day of October, premiums will be awarded the owners and ploughmen of the three ploughs drawn by one yoke of oxen which shall be judged by the Committee to have performed the best work with the least expense of time and labor, not exceeding an eighth of an acre to each plough, and to the three ploughs which shall have ploughed one quarter of an acre with two yoke of oxen that shall be adjudged to have performed the best work with the least expense of labor. There will be two Committees of three persons each, the one to be judges of the ploughing by one yoke of cattle, the other of the ploughing by two yoke of cattle. Notice to be given, at least, fourteen days before the aforesaid 16th of October, that the ground is prepared and may be examined by those disposed to compete for the premium which are as follows (being the same for double as single teams):—

First Plough, \$15	Second Plough, \$10
Ploughman, 8	Ploughman 5
Driver, 4	Driver, 3
\$27	\$18
Third Plough, \$6	
Ploughman, 3	
Driver, 2	

\$11

The sum assigned for driver to be awarded ploughman in each case of no driver. The person intending to compete for these prizes must give notice to Gersham Parsons, or Mr. Francis Winship, of Brighton, by letter, post paid, or by personal application, on or before the 15th of October, the day previous to the Ploughing Match. The competitors will be considered as agreeing to follow such rules and regulations as may be adopted by the Committee. The satisfaction expressed by the agriculturists who have attended the Ploughing Matches for several years past, will induce the Society to continue their premiums annually in connexion with the Cattle Show, believing it an efficacious means of exciting emulation and improvement in the use and construction of the most important instrument of agriculture.

GERSHAM PARSONS, Per Order.

Brighton, Sept. 27, 1823.

N. B. It must be understood by the competitors that the furrows must not exceed ten inches in width.

The Middlesex Cattle Show of which we have given an official account, in the preceding pages, is spoken of in terms of high approbation by well qualified judges who were present. We have only to regret that indispensable avocations (caused in part, by the absence, on a journey of the Proprietor of this paper) kept the Editor, as it were, tethered in Boston. Notwithstanding our wish to greet our Concord friends, and enjoy their society, witness and applaud their improvements, partake of their festivity, and see and hear the fat, fair, fine, facetious, ingenious, useful, scintillating

mental and patriotic things which they had to offer on occasion, imperious necessity kept us chained to dull pursuits of a printing office and Editorial closet. We beg leave, however, to assure the SOCIETY OF POLYTES HUSBANDS AND MANUFACTURERS, whether personally present or absent our best efforts always attend them, and our best exertions are at their service.

Lockingham Agricultural Society (N. H.) will hold a Show on the 15th and 16th day of the present month.

Contributions for the sufferers by fire in Maine have been liberal—honorable to our countrymen and to humanity. In the several churches in this city, according to the Centinel, on Sunday last, they amounted to \$453. In Salem \$841 67. In Beverly, \$133 98. Newburyport \$514 36.

FOREIGN.

There have been no arrivals from Europe since our last; and there is but little to be gleaned from European papers worth recording, which is not altogether of date. The King of Spain has been happily decorated before the Cortes, of a long patriotic speech, which, if sincerity is a prominent feature we very much mistake the matter. In this speech the "French rulers" are execrated, most cordially, as "hypocrites, liars" and other hard things, and said to place more reliance on "corrupting gold than their own valour." The Cortes are eulogized in due proportion to the anathema bestowed on the French—But the whole is not worth a potatoe top and is therefore omitted. There have likewise some French and Spanish bulletins which are as fairly at war with each other as their authors, a real matter of fact is not to be had for a premium among such dealers in tough stories. We must not for time to teach us what the mad caps and hairpins of Europe are about, and bless our stars that we have nothing to do with them nor their quarrels.

DOMESTIC.

Large Water Melon.—A water melon was served up on the table of the Cincinnati Hotel on the 8th ult. weighing sixty one pounds, being 2 feet 8 inches in length, and 3 feet and 1 inch in circumference.

N. Y. Com. Advertiser.

Great Turnip.—Taken from the garden of Mr. J. B. Swasey in Mercedith on the 15th inst. a Turnip, the circumference of which was 3 feet 2 inches, length of root 2 feet 3 inches, and weighed 42 and a half pounds. Weighed and measured by Rev. Parker Esq. and Maj. Daniel Hilton.—N. H. Pat.

A swarm of Bees, taken up by Richard Bradley, in this town last week, yielded in weight of honey and comb, one hundred and sixty-five pounds.—ib.

Maine Canal.—A Canal is about to be opened in Maine, and will be completed in June next, connecting the waters of Penobscot Lake with Penobscot River, by cutting through the Kenduskeag, six miles above its confluence with the Penobscot, at Bangor, affording several valuable mill privileges, and through which the town of Bangor will receive an immense quantity of lumber and other property, which heretofore, in consequence of the difficulty of getting it to market, has been of little value.

Culture of the Grape.—A vineyard of A. Eichelberger, in York, Penn. contains 10 acres, covered with vines of Lisbon, white, and other grapes. He will take 40 barrels of wine this season, and he intends to extend his vineyard to 20 acres next year.

Two persons suffocated in a well.—At Barre, Vt. a deep well descended into a deep well for the purpose of boring up a drill, but after descending to the bottom the thing could be heard from him. Mr. Amariah Peck, an old gentleman aged 80 years, descended in hopes to

save the rail, but perished in the attempt. After a few bodies were taken from the well a lighted candle was let down, but would not burn within a considerable distance of the bottom.

Agricultural Diplomas.—An advertisement lately handed in, induced us to look at a copy of an engraving by Mr. Balch, formerly of Albany, for the Diplomas of Agricultural Societies. The design and the execution are very beautiful, and we presume that when sent, copies will be readily purchased by the proper agents of these institutions throughout the State.

Con. Mirror.

Child burnt to death.—Last Tuesday afternoon, a child of five years old, daughter of Mr. Joseph Miller, of East Hartford, was left for a minute or two near a fire, which caught her clothes, and she was hurried to death. We do not mention this to gratify that taste for the horrid which is so common among newspaper readers, for it is worse than useless to tell every tale of suffering, when no practical good can result from it, but whenever an accident occurs to which others, if not cautioned are liable—such occurrences should be stated. The clothes of the child were of cotton, and we all know how easily such stuffs burn. Woolen is as cheap and as durable—and now as the season approaches when fire is needed, let us suggest to those who have children to clothe, that it would be advisable to dress them in *woollen*.—ibid.

A late arrival at Norfolk from Thompson's Island brings melancholy news from that quarter. Captain Watson, Lieutenants Hammersley and Carter, Sailing Master Bainbridge, Midshipmen Benbridge and Taylor, Chaplain Adams of New Hampshire; and about forty seamen have fallen victims to fever. About sixty other cases are said to be existing. Commodore Porter was much better.

A letter from Gibraltar, dated September 3d, states, that the French had been repulsed at Tarifa, with the loss, it was reported, of 800 men. The writer adds, "Malaga is in a dreadful state at present; the commander has made a requisition of 100,000 dollars of the merchants—several who refused to pay, have been sent to prison, among them the American Consul, and several have been shot. The English frigate Tribune is so proceed from here to bring the English merchants from that place."—Boston Gazette.

Accounts from St. Louis state, that some of the Scotch and Swiss emigrants planted by Lord Selkirk on the Red River of Hudson's Bay, are making their way to the United States, finding the severe climate of that latitude unbearable.

By way of St. Louis we learn, also, from St. Anthony, that an engagement had recently taken place between the Sac and Sioux Indians, in which the former had 7 killed and 12 or 15 wounded, and the latter, 11 killed and 12 wounded.—ibid.

Burlington, Vt. Oct. 3.—Passed this place on Friday last, the Canal Boat *Gleaner*, Capt. Burton, on her return to St. Albans from New York city. The Canal Boat *Terrant*, Capt. Lyon, arrived here on Wednesday last from Troy. Both boats were richly laden with merchandise.—ibid.

The Secretary of the Navy has directed a special mission to be sent to Key West (Thompson's Island) for the purpose of examining into the causes of the disease existing there; with authority to discontinue the naval station there, should it be found necessary. Commodore Rodgers has volunteered his services for the occasion, and is to have with him four of the oldest naval surgeons. It is expected they will be gone four or five weeks.

Snow.—There was a considerable fall of snow at and around Belfast, Maine, on the night of the 29th ult. In some of the back towns it fell to the depth of six inches.

Agricultural novelty.—Some blossoms from a pear tree were yesterday shown us, which we understood bore fruit a week since, and is now in full bloom. Some of the fruit is yet remaining on the tree, a deep-seated striking contrast to the numerous blossoms by

which it is surrounded. The pear is of French origin, called *le Bon-Charbon*. A circumstance of this sort is superstitiously regarded as the precursor of the death of the tree the following year; but the tree referred to, was, we are told, visited by a similar occurrence about ten years ago.—Continued.

ALDERNEY BULL FOR SALE.

THE very fine full blood ALDERNEY BULL, which was presented to the Massachusetts Society for promoting Agriculture by John Hubbard, Esq. This breed is considered in England, as superior for the richness of their milk, making considerable more butter from the same quantity of milk, than any other breed. He is now two years and three months old, is in fine health, and a gentle animal, and may be seen at the farm of John Prince, Esq. Jamaica Plain, Roxbury. For terms of sale, which will be very liberal, apply to JOHN LOWELL, Esq. or said Prince, in Roxbury.

If the above animal is not previously disposed of, he will be at the Public Show at Brighton, on THURSDAY 16th October, at 12 o'clock.

Roxbury 30th Sept. 1823.

FOR THE NEW ENGLAND FARMER.

THE YEOMAN.

Happy the man, who courts a country life,
And holds no stake in mad ambition's strife,
Where every rogue would fain supplant his brother,
And men seem born to worry one another;
And women too—but pray, Miss Muse! stop there—
We never permit you to abuse the FAIR.—
The man is blest who shuns each bustling mart,
The proud emporium of each useless art,
Whom Nature's simplest blessings can please,
Whose days are spent in exercise and ease,
Without those cares, which pride and wealth annoy,
And dash with poison Grandeur's cup of Joy.
He gathers Health from herbs the forest yields,
And culls his physic from the flowery fields.
Thus lives a stranger to each deadly ill,
Whose *ne plus ultra* is the Doctor's bill.
His heart is large, although his means are small,
His door still open to the needy's call;
But in his dealings so correct and square,
Lawyers and sheriffs have no business there.
No duns put off with "please to call again,"
And Charity ne'er asks his boon in vain.
This man enjoys more real bliss below
Than kings possess or nobles ever know.

From the President of the New-York Lyceum of
Natural History, to the Members, dated New-
York, Sept. 11, 1823.

THE VAMPIRE OF THE OCEAN.

On the 9th day of September, 1823, returned from a cruise off Delaware Bay, the fishing smack Una. She had sailed about three weeks before from New York, for the express purpose of catching an enormous fish, which had been reported to frequent the ocean a few leagues beyond Cape May and Cape Heolopen. The adventurers in this bold enterprize have been successful. They have brought for the enlargement of science and the gratification of curiosity, an *unprecedented* inhabitant of the deep, which has never been seen on the land before.

The creature is one of the huge individuals of the family of *Raja*; or perhaps may be erected, from its novelty and peculiarity, into a new genus, between *that*, the *Squalus*, and the *Scipencer*. Its strength was such that after the body had been penetrated by two strong and well formed gigs of the best tempered iron, the shank of one of them was broken off, and the other singularly bent. The boat, containing the three intrepid men, John Patchen, Theophilus Beebe, and William Potter, was connected, after the deadly instrument had taken hold, with the wounded inhabitant of the deep, by a strong warp or line. The celerity with which he swam, could only be compared to that of the harpooned whale, dragging the boat after it with such speed as to cause a wave to rise on each side of the furrow in which he moved, several feet higher than the boat itself.

The weight of the fish after death was such that three pair of oxen, one horse, and twenty-two men, all pulling together, with the surge of the Atlantic wave to help, could not convey it far to the dry beach. It was estimated from this, and a probable estimate, to equal four tons and a half, or perhaps five tons.

The size was enormous; for the distance from the extremity of one wing or pectoral fin

to the other, expanded like the wing of an eagle, measures, 18 feet.

Over the convexity of the back, and on the right line of the belly, . . . 16 feet.

The distance, from the snout to the end of the tail, 14 feet.

Length of the tail, 4 feet.

Width of the mouth, 2 ft. 9 in.

The operation of combat and killing lasted nine hours. It was a heroic achievement, and was witnessed by crowds of citizens on the shores of New-Jersey and Delaware, and by persons on board the flotilla of vessels in the bay and offing.

During the scuffle, the wings, side flaps or vast alated fins of the monster, lashed the sea with such vehemence that the spray rose to the height of thirty feet, and rained round to the distance of fifty feet. It was a tremendous encounter. On shore all was awe and expectation.

Mr. Patchen, whose taste and zeal in zoology are well known, has attended very much to the manners of the *Vampire* of the Ocean, to the preservation of the skin and external parts, to the osteology and skeleton, the internal organizations; and in short, to every circumstance that was practicable during such a hazardous business and the tempestuous weather which distressed them almost from the beginning to the end of their voyage.

I merely mention, before I lay down my pen, that this animal is viviparous, and of course connects fishes with mammiferous animals; and that the respiratory, motory, and generative and sensitive organs, present an extraordinary amount of rare and interesting particulars. Incomprehensible as well as wonderful are thy works, O Creator! in consummate sagacity thou hast executed them all!

This is but an outline; I intend to finish this sketch; and prepare it as well as I can for the Society's formal notice.

While I express full approbation of our friends, whom neither difficulty nor danger could discourage, I utter a further sentiment that they may be well repaid by their intended exhibition. SAMUEL L. MITCHELL.

Ingenious and useful invention.—Amongst the new Parisian inventions is a coffee pot constructed of three pieces: the first is a plain boiler, over that is a double filterer, and at the top is an inverted coffee pot, which fits on exactly. Cold water is placed in the first vessel, and the coffee in the filtering pot. Under the whole is a spirit lamp, which in the course of five or six minutes causes the water to boil, the vapor arising from which completely saturates the coffee. When the water boils, which is ascertained by the discharge of the vapor from the spout of the inverted coffee pot, the whole machine is lifted from the lamp, and completely inverted so that the pot, which was uppermost, is at the bottom, and the boiling water, which had saturated the coffee, flows through the filterer, clear, into what was before the inverted coffee pot, where, in the space of two minutes, it is ready for use. This mode of preparing coffee is a saving of at least 25 per cent. and it secures the fine flavor of the berry. In another part of the service is a coffee master of glass, over another lamp of a long wide flame. The roasting requires about

three minutes, and even so small a quantity an ounce may be thus prepared.

York (Eng.) Musical Festival.—It is computed that the necessary expenditure in this grand undertaking, which has the patronage of 5 dukes and lords for aiding the respective funds of the four general infirmaries in this county will not be less than 7000*l*. 133 instruments performers are already engaged and 264 vocal viz. 72 cantos, 60 counters, 60 tenors, 72 bases. Charity being the object of the performance and the period fixed upon immediately after Donchester races, the promoters calculate upon the largest assemblage of company that ever took place on a similar occasion.

FRUIT & ORNAMENTAL TREES.

FOR SALE, as usual, at the KENRICK PLACE, near Brighton. The Nurseries have been much enlarged, and contain a variety of Pears, Apples, Cherries, Plums, Apricots, &c. Also, the finest Nursery of budded Peach-Trees known in America; consisting of a choice collection of about 30 of the most approved kinds in our best gardens, or seen in the Markets. The trees are from 5 to 2 feet high, and sold at the Nursery at the moderate price of 3*s* 1*d* 3 cents each.

Of good sized ornamental trees; the Flowering Horse-Chestnut; Flowering Catalpa; European Mountain-Ash; Weeping Willow; the evergreen Silver Fir, and the Larch. English Walnuts and Butternuts, both of which are justly admired for their fruit. The latter is a hardy, handsome tree, and its bark valuable as dyes and medicine.

Current bushes of the large prolific red kind, of all sizes, by the dozen, hundred, or thousand, on moderate terms: Also the Black, White, and Champaigdo. Red and White Roses; Lilacs; English Grapes; Gooseberries, &c. &c.

Orders addressed to John, or William Kenrick, and sent to the Brighton Post-office, or the Office of Mr. Samuel Dana, Broker, in Congress-street, Boston, will be duly attended to.

N. B. Trees will be packed in clay and mats, for shipping, and conveyed to Boston when ordered; but gentlemen at a distance should employ some agent to receive and pay for them.

Oct. 4.

NEW ENGLAND MUSEUM,

76, COURT STREET, BOSTON.

CONTAINING much more numerous Collection and greater variety of entertainments than any other Establishment in America, continues steadily to increase, and is open for the reception of visitors.

EVERY DAY AND EVENING.

It will be constantly in the best possible condition, and every exertion made to render the visits of its patrons agreeable.

This Establishment now contains FIVE former Museums united in ONE, together with very great and numerous additions (the whole receipts being faithfully laid out to increase it.)

JUST ADDED,

The celebrated Race Horse Eclipse,
A beautiful Cosmorama View of London,
A large and beautiful live Rattlesnake,
The Arabian Bottle, made of the stomach of a Camel—holds about a barrel—used to carry water across the desert.

The Invalid's Chair—very ingenious—invented by Professor Peck.

A very large and elegant Sword Fish, upwards of 14 feet long, with a sword 4 1-2 feet long.

There is also now residing in the Museum, Mr. JOSEPH M. STREVEN, the most remarkable Dwarf ever witnessed in the U. States. He is handsome, cheerful, and gentlemanly in his deportment; in his 30th year; 37 1-2 inches high, and weighs 34 lbs.

The Museum is well lighted, and a Band of Music performs every evening. Admittance 25 cents.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

ON MAKING AND PRESERVING CIDER.

[Concluded from p. 73.]

3. It is often the case that those who undertake to be very philosophical in the process of manufacturing cider, make a troublesome and expensive job of it, and after all, spoil their cider. They cause it to undergo so many fermentations, while exposed to the open air, that it loses all its carbonic acid gas, or fixed air, and perhaps, a part of its alcohol, or vinous spirit. If the whole fermentation, which is necessary to change the raw apple juice into cider, and rich cider could be conducted in close vessels, according to Dr. Darwin's theory, as in paragraph 11, page 73, the products of the fermentation, which are alcohol, and carbonic acid gas, would be preserved, become incorporated with the liquor, and cause it to be clear and lively, without being harsh and heady. Exposing new cider in open vessels, till the vinous fermentation has produced its results, carbonic acid gas is expelled, but a part of the alcohol is retained. Hence vinegar will infiltrate, if drank in sufficient quantity. But carbonic acid gas, retained in cider, properly manufactured, exhilarates, without inebriating, stimulates and enlivens, instead of operating like an opiate, and causing those who drink it to become at once wild and stupid. It is the want of understanding these principles which leads many would-be philosophical geniuses to doctor their cider, and punish themselves by drinking off the dead liquor. They rack and rack, and rack super-fine their cider till it becomes as dish water, and as sour as lemon juice, something which tastes like a compound of all those articles. It is much better to proceed according to a common practice of New England cider-making, viz. Take the must, or raw cider directly from the press. Strain it through straw or a coarse sieve into clean and new casks, give it no more vent during fermentation than is necessary to prevent the bursting of the vessels, and not draw off till it is ready for use. It is necessary, however, during fermentation to keep the casks full that the scum which rises may be thrown out of the

It was well observed by Mr. Winkley, in a communication respecting the mode of making cider, adopted by the religious society, called Sakers, (republished from the Massachusetts Agricultural Repository, in our paper, vol. No. 43, p. 377) that "the slower cider ferments, the better it will be." The reasons are these—If cider ferments slowly, it gradually stops working at the end of the vinous fermentation, and does not pass to the acetous fermentation, which would convert it into vinegar. And if the fermentation proceeds slowly, the fixed air has time to combine, and become incorporated with the liquor instead of escaping into the atmosphere. By mixing a proper quantity of alcohol (spirit of any kind) with cider from the press, you may stop the acetous, and course prevent the putrid fermentation.

But the spirit so mixed hastens the vinous fermentation, which, as before observed, is the only fermentation which can be suffered in making good cider. The alcohol will check the turbulence of the fermenting liquor, by combining with the carbonic acid gas, which causes the fretting and fuming as well as gives the life of the liquor. Thus Nicholson's Fourcroy (Art. Alcohol) says, "*alcohol dissolves the carbonic acid gas, which it condenses and liquefies more than in the proportion of a volume equal to its own.*"

15. We learn that the Religious Society, mentioned above, make use of cider-spirit, distilled from the lees of cider, to regulate the fermentation of their new cider and fit it for the table. They do not, however, make use of their cider-spirit till they have racked off their cider, about the first of January. They then add from one to three gallons of the spirit to a barrel of cider, and "bung it down air tight, and let it stand till it becomes of mature age." This appears to have been the principal improvement, which has rendered the cider manufactured by the Society so famous, and caused it to command an extraordinary price in market. A friend of ours, however, has a mode of using the cider-spirit in refining his cider still less troublesome, and we believe at least equally efficacious. This gentleman mixes from one to two gallons of cider brandy with his cider, when fresh from the press, and immediately closes the barrel perfectly air tight. In about a month's time, in the ordinary temperature of a common cellar in the latter part of autumn, his cider is perfectly fermented, and purified, so as to be in its best state for the table, without the trouble of stumming his casks with brimstone, and hazard of their bursting, or any necessity of racking off his liquor.

16. The quantity of spirit to be thus mixed with cider, we conclude should be in some proportion to the strength of the must. If that contains a good deal of spirit it will ferment quietly and quickly, otherwise it will be turbulent, and must have vent, or it will endanger the vessel which contains it, and soon become flat and sour. The same thing will take place with malt liquor. Ale, or strong beer, which contains considerable alcohol, can be bottled without difficulty; but small beer, which has but little alcohol, is apt to burst the bottles. And in bottling cider a spoonful or two of brandy, or other spirit mixed with the cider in the bottles will prevent that violent effervescence, which might otherwise burst the bottles. Some writers say, that sugar, honey, molasses, or other sweet substances mixed with new cider, will strengthen it, and prevent its fermenting to excess. This is probable, for any sweet substance mixed with a due quantity of water, or other mild liquid will generate alcohol, and the latter will combine with the fixed air, and thus put a stop to its turbulence. But, doubtless, to fine cider with saccharine matter would require a longer time than with alcohol, and we doubt whether it would be so safe or so effectual to use the former as the latter in close vessels.

* See N. E. Farmer, vol. i. p. 377.

17. An English writer says, that an infusion of hops is used in cider to give it a flavor, and an agreeable bitter. Another recommends grinding elder berries with the fruit, which gives the cider a fine color as well as flavor. Rye whiskey is likewise recommended as a good substitute for cider-spirit to mix with new cider. Ginger, cinnamon, spices, raisins, &c. have their advocates who assure us they are very good ingredients in cider. But we believe genuine cider-drinkers prefer the clear apple juice. Some advise to make use of bullock's blood, calf's feet jelly, isinglass, &c. &c. which may be well if the cider needs doctoring, but we believe it best to make vinegar of cider which requires to be medicated with such materials to render it palatable and wholesome.

18. The Complete Farmer's Dictionary says, that "the best shaped vessels for keeping cider in are those in which the barrel boards are straight, the vessel broader at one end than the other, and standing on the lesser end with the bung hole in the top. The advantage of this form is that in drawing off the cider, though but slowly, the skin or cream, contracted by its fermentation descends and covers the liquor by means of the tapering of the vessel, and thereby preserves to the last the spirits of the cider, which would otherwise evaporate and waste." A sensible writer, whose essay was republished from the "Farmer's Weekly Messenger," in our vol. i. p. 153, has made it apparent that white oak iron bound hogsheads, made of heart stuff, well painted, and of a size to hold about three barrels and a half, and smeared over with some kind of refuse oil, with a little Spanish brown and lamp black, once in three years will prove more convenient and economical than such barrels as are commonly used. Besides cider ferments more kindly, and keeps better in large than in small vessels. Beer vessels are said to be bad for cider. They spoil cider, and cider spoils beer. New vessels made of seasoned oak do well; but those which have been used do better. The Religious Society mentioned above, clean casks by taking them from the cellar as soon as convenient after the cider is out, (reserving the lees for stilling) and rinse each clean, first with a pail full of scalding water, then with cold, leaving the casks with the bungs down for a day or two. They are then bunged tight and returned to the cellar, or some convenient place, proper for their reception. Previous to filling the casks for the season they are scalded and rinsed as above mentioned.

19. Mr. J. Hommedieu, of New York, directs, when casks have more or less of a sour or musty smell, to take at the rate of about a pint of unslacked lime for a barrel, put it in and pour in three or four gallons of hot water, or more for a larger cask; shake it well, giving it some vent; let it stand till cooled, and then rinse it with cold water. This operation to be repeated till the cask smells perfectly sweet. Stumming casks, or fumigating them, together with the cider may be advisable, especially when spirit is not incorporated with the cider when fresh from the press. Stumming is thus performed. Take a strip of canvas cloth, about

twelve inches long and two broad; let it be dipped into melted brimstone; when the match is dry let it be lighted and suspended from the bung of a cask (in which there are a few gallons of cider) until it be burnt out. The cask must remain stopped for an hour or more and then rolled to and fro, to incorporate the fumes of the match with the cider; after which the cask may be filled. If the stumping be designed only to suppress improper fermentation, the brimstone match is sufficient; but if it be required to give any additional flavor to the cider, some powdered ginger, cloves, or cinnamon, &c. may be strewed on the match when it is made.

CHESHIRE AGRICULTURAL SOCIETY.

The annual Cattle Show and Exhibition of Manufactures for the County of Cheshire, was held at Westmoreland on Wednesday the first instant.

An assemblage of a large number of our wealthy, intelligent and experienced farmers afforded the gratifying assurance that an undiminished interest is still felt in the concerns of the Agricultural Society.—The previous arrangements for the day were carried fully into effect.

The awarding committees, previously appointed, attended and discharged their duties promptly and judiciously.

In the morning the hours from 8 to 10 o'clock were devoted by the Society to the transaction of business.—About twenty new members were admitted.—The following officers were elected for the ensuing year:—

Samuel Findlay, of Acworth, *Pres.*; Stephen Johnson, Walpole, *1st Vice Pres.*; Elijah Belding, Swansey, *2d Vice Pres.*; Thomas M. Edwards, Keene, *Secretary*; Daniel Bradford, do. *Treasurer*; Martin Butterfield, jr. Walpole, *Librarian*; Thomas C. Drew, of Walpole, Aaron Hodskins, do. Simon Cobb, Westmoreland, Salma Hale, Keene, Ephraim K. Frost, Swansey, Elijah Alexander, Winchester, *Executive Committee*.

At 12 o'clock, as is usual the Society formed in procession, and under the direction of Captains Greene and Wheeler, proceeded to the meeting house. After appropriate Services of prayer and music, an address suitable to the occasion was delivered, and the reports of the several awarding committees were read.—The address by Mr. John Lancaster was an ingenious and sensible performance—full of suggestions relating to almost every branch of husbandry.

The Society returned and partook of an excellent dinner prepared by Samuel Winchester.

The exhibition was highly respectable. In stock it perhaps cannot be said to have been superior to some which have preceded it. The number of animals presented was hardly as large as on some former occasions, though many of them were of the very first class.—The working oxen and young stock were particularly good. The value of the former was tested by actual trial. The drawing match afforded a fine display of activity and strength.

In the other branch of the exhibition there was a decided superiority.

The specimens of woollen and linen Cloths, and flannels, were honorable to the competitors, and displayed a perfection in household manu-

factures which until within a few years was wholly unknown in our County. The grass bonnet, presented by Miss Parker, was a successful imitation of the finest quality of the tasteful and expensive Leghorn, and very justly much admired.

The following reports of the awarding committees render any further particulars unnecessary.

ON WORKING OXEN AND STEERS.

The Committee, consisting of Aaron Hodskins, of Walpole, Jotham Lord, jr. Westmoreland, Elijah Parker, Keene, and Leonard Thayer, of Acworth, having examined all the Oxen offered for premiums, and observed their strength and skill in drawing, award—

To Jesseiah Kittredge, of Walpole, the first premium on a pair of 6 years old working oxen, \$10
To Samuel Wadsworth, of Roxbury, the second premium on a pair of 6 years old working oxen, 7
To Samuel Lincoln, of Westmoreland, on a pair of 2 years old steers, the first premium, 8
To Samuel Lincoln, on a pair of 3 years old steers, the 2d premium, 6

The committee would observe that many other fine pairs of oxen were exhibited. That they noticed a number of fine teams which were brought on to the ground, though not entered for premiums. And that from the examination of the whole and of many fine steers which were presented, they are convinced that there has been among our farmers, within a few years, a very apparent improvement in the stock and breed of cattle.

AARON HODSKINS,
Chairman, for the Committee.

ON COWS AND HEIFERS.

The Committee, consisting of James M. Warner, of Acworth, Chairman; Samuel Grant, of Walpole, Moses Chamberlain, of Winchester, and Isaac Hubbard, of Claremont, award—

To Seth Morton, of Langdon—the first premium on Cows from 4 to 5 years old, \$5
To Philus Hodges, of Westmoreland, the 2d do. 6
To Nathaniel Holland, of Walpole, for the best Heifer from 1 to 4 years old, the first premium on Heifers, 6
To James Gilchrist, of Charlestown, for the next best 2d premium, 4

Several other fine cows and heifers were exhibited; a cow by Benjamin Doolittle, of Winchester. A heifer by Dr. Twitchell, of Keene, one by William Bullum, of Walpole, and one by James Gilchrist, of Charlestown, and one by Nathaniel Holland, of Walpole, were among the best. Between the heifer presented by William Bullum and the one to which the second premium was awarded, the Committee found much difficulty in deciding.

JAMES M. WARNER,
for the Committee.

ON BULLS, SHEEP AND SWINE.

The Committee, consisting of David Parker, of Charlestown, Daniel Robinson, of Acworth, and Ezra Parker, of Winchester, having attended to their duty award—

To James Dickey, of Acworth, for the best bull, being 3 years old, of the Yorkshire breed, having been kept in the County 3 months, the first premiums on bulls, \$12
To Jotham Lord, jr. of Westmoreland, for next best do. 19 months old and of the Yorkshire breed, the 2d premium, 8
To William Jennison, of Walpole, for the best Mervin Buck, kept in the County one year, 1st premium, 5

To William Jennison, of Walpole, for the next best do. 2d premium,

To Aaron Hodskins, of Walpole, for the two best pigs, the 1st premium on pigs not over 9 months, To Aaron Hodskins, of Walpole, for the 2 next best, do. the 2d premium,

Four very fine pigs were offered by Zephaniah Witherell, of Westmoreland.

DAVID PARKER,
for the Committee.

ON LEATHER.

The committee, consisting of Thomas Ames, of Keene, Chairman, Lemuel Lincoln, John Carlisle, Nathan Vilas, Samuel Winchester, award—

To Jonathan H. Chase, of Walpole, for the best manufactured 2 sides of upper leather, To Edward Wittington, of Chesterfield, for the best manufactured 6 calf skins, To Daniel Reed, of Fitzwilliam, for the next 3 best do.

THOMAS F. AMES,
for the Committee.

ON LINEN MANUFACTURES, HATS & BONNETS.

The committee, consisting of Thomas Drew, of Walpole, Chairman, Larkin Baker, Westmoreland, and Vrylug Lovell, of Charlestown, award—

To Jane Robb, of Acworth, the first premium on linen diaper, To John Lancaster, of Acworth the 2d do. To Elizabeth Pinkerton, of Acworth, the first premium on linen cloth, To Peggy McClure, of Acworth, for the best Cotton Counterpane, To Mrs. Josiah Bellows, 2d of Walpole, for the next best do. To Silvia Parker, of Fitzwilliam, for the best grass bonnet, To Betsey Ruggles, of Walpole, for the two best straw bonnets, To Dexter Anderson, of Walpole, for the six best manufactured for hats,

The Committee examined a number of piece of linen and diaper but little inferior in quality to those to which they have awarded premium. A piece of linen diaper by Miss P. McClure was very finely manufactured. The exhibition of linens was much superior to that of the preceding year. The grass bonnets by Miss Parker deserve particular notice. The finest is at least equal to No. 50, of the Leghorns. Some articles were exhibited upon which the Committee are not authorized to award premiums: of these they can only express their opinion. A valise was presented by Ursilla Gaffield, of Charlestown, which evinced much taste and skill in the manufacturer. A quantity of shirting from the Factory at Chesterfield was good. A cotton and woollen Counterpane, by Mr. Jennison, was ingeniously made, a quantity of linen thread, by Miss McClure and Miss Pinkerton was equal to the best imported.

THOMAS C. DREW,
for the Committee.

ON WOOLLEN MANUFACTURES.

The Committee, consisting of Jimna Walker, of Westmoreland, Gaven Gilmore, of Acworth, and Martin Butterfield, jun. of Drewsville, award

To Josiah White, of Charlestown, for the best piece of dressed woollen cloth, the first premium, To Samuel Findlay, of Acworth, for the next best do. 2d premium, To Josiah White, of Charlestown, for the best piece of Kerseyware, To Josiah White, for the best piece of flannel,

Mary Chase, of Lempster, for the next best, Samuel Findlay, of Acworth, for the best pair of woollen blankets,

Minwell Campbells, for the next do.

Samuel Findlay, of Acworth, for the best woollen coverlet.

Mrs. Josiah Bellows, 2d, of Walpole, for the best piece of carpeting, length 25 yards, width, 1 yd.

The Committee, in awarding the above premiums, believe they should do injustice to many of the Competitors to pass them unnoticed. A number of pieces of woollen cloth were presented, of very excellent stock and well manufactured. A piece by Samuel Dinsmoor, was very nice, unquestionably the third best piece exhibited. The woollen manufactures, generally, with the exception of the woollen shawls, are of superior quality. The shawls were ordinary, and not thought deserving of a premium. The Committee, in withholding this premium, would express the hope that more attention will be paid to the manufacture of this article for a succeeding exhibition.

They would also notice a number of hearth-rugs—one by Mrs. Joseph Dorr, of Keene; 2 Mrs. Abel Bellows, of Walpole; 1 by Mrs. Dunbar, of Keene. The preference was given to Mrs. Dorr's; although all were much admired. They would also mention two pair of woollen hose, by Mary Carlisle, of Westmoreland.

JIMNA WALKER,
for the Committee.

[From the New Hampshire Patriot.]

HILLSBOROUGH CATTLE SHOW.

REPORT

Of the Committee on Working Cattle.

The committee, appointed to examine the merits of Working Cattle, and to adjudge the prizes, have attended to the duties of their office, and beg leave to report.

Agreeably in their instructions, they have taken into consideration not only the ploughing, but the goodness of the cattle, time, &c. What was now much was intended by the &c. your committee were unable to determine; but they presumed that it embraced, or might embrace the discipline of cattle, and they have brought it into estimate in making their decision. That cattle, destined for labor, should be well broken to the yoke, and submit to the authority of the master, is universally admitted, and generally practised. But it is of great importance that they be trained to exercise the plough without a driver.

This is easily effected; and it is a great saving of expense in the cultivation of fields. Most of our ploughing can be done by one yoke of oxen; and with little attention they will perform as much labor on the plough without, as a driver. Even two yoke may easily be taught to do the same. By using the most active and highest spirited pair for leaders, there will be little or no difficulty attending the practice. To save the expense of a man, or even a boy, will be no small additions to the interest of the farmer. It is equally important to reduce the expense of cultivation, as it is to increase the quantity and value of crops.

While we make our observations upon cattle, we would not pass by the teamster with neglect. We cannot forbear to remark on the excessive use of the whip, though there is not so much cause of complaint as there was the last year. Men that are well disciplined, will do all they are taught to do, and they will do all they can do

without severe whipping. That the Ox, that most useful animal, that most faithful servant of man, distinguished for his patience and industry, pre-eminent among the herd of the stall, whose tongue was never defiled by an indecent, or profane word, whose breath was never polluted by the fumes of intoxication, and before whom the Egyptians bowed down in devout adoration, that the ox, I say, should be the object of the unmerciful scourge is an outrage upon that law, which has given to man dominion over the beasts of the field.

After trying the oxen presented, on the drag and on the plough, the committees have come to the following decision, and they make the following awards.

To Mark Morse, the committee award the first premium on Working Cattle. Taking into view the age, form, size, strength and activity of his cattle, they came to this result.

To Moses Greene is awarded the second premium. His cattle are five years old, measure 7 feet, 3 inches; they are remarkable for their strength; and they work with a good degree of activity. They are in a high state for beef, though they have done the necessary work on his farm, the past season.

To David Danforth is given the third premium. His cattle are five years old, of large size, good form and discipline, great activity, and promise to be very useful. These points led to the decision.

The fourth premium is awarded to John Johnson. His cattle are large, fleshy, strong, and performed his work very well.

Other cattle richly deserved premium; and it was with some difficulty a selection was made. The committee, though past the meridian of life, decided as if they believed that advanced age was derogatory to character, or promising usefulness. Mr. B. Parker, and Mr. Joseph Kingsbury, presented no statements respecting their cattle, agreeably to the regulations prescribed.

The ploughing match demands a few remarks. It was cause of regret that a more suitable piece of ground could not have been selected for the purpose. The land was laid out into plots of about one eighth of an acre each. There was a little difference in their size, a little difference in the quality of the work, a little difference in goodness and breadth of the ploughs, and a little difference in the time of performing the work. The average time was from 10 to 11 minutes, exceeding in shortness of time what has ever been done before in this Society.

Fourteen yoke of cattle were entered for premiums, and thirteen entered the list for competition. They all excelled in some points; but as only four premiums were offered the expectations of some must, of course, be disappointed. The general character of the Working Cattle was excellent; and though some of them could not draw a premium they could draw as much upon a drag, as the most highly favored oxen.

The progress, which is making in this department of stock is highly pleasing; and encourages the farmer to persevere in his exertions for improvement. It is hoped that all will give a hand to the work, in which they are all equally interested.

Respectfully submitted by your committee.

HUMPHREY MOOR,

in behalf of the committee.

Francesstown, Sept. 25, 1823.

Grafton County Cattle Show.—One of our Agricultural friends in the County of Grafton writes to us,—Our Agricultural Society held their annual Exhibition and Fair, at Lyme on Wednesday the 1st inst. The stock in general, though not numerous, was of the best quality, and the same may be said of the Domestic Manufactures. The large concourse of independent and practical farmers assembled on the occasion manifested great delight with the various exhibitions of the day, and particularly with the very able, scientific, and practical address from Prof. Dana.

I understand the Society have requested a copy for publication, and I sincerely hope the public will speedily be gratified with its perusal. A regular account of the Society's proceedings will soon be communicated for the Patriot." *Ibid.*

Children's Food.—A lady of Yorkshire observes in a letter dated May 2, that, in consequence of her losing first three children, one during teething, and two of inflammation in the bowels she gave her fourth child a little lime water every article of food adding a dessert, and sometimes only a tea spoonful of lime water to every article whether liquid or thick. It succeeded in keeping up healthy digestion, and a regular state of the bowels; the child, instead of being feverish, flatulent, and fretful, as her preceding children had been, continued cool and cheerful, free from any symptom of indigestion, and cut its teeth without any constitutional disturbance. She has continued this practice with two more children with the same good effects. We have known this simple addition to the food of children prove very efficacious in incipient cases of rickets and of irritable bowels, attended with looseness, &c.; but if the child be disposed to costiveness on account of its assurgent quality a little magnesia should be occasionally added to it.—*Gazette of Health.*

An extraordinary case of hydrocephalus, or water of the brain, is just now exciting the interest of the medical gentlemen of Salisbury. The head of an infant, before any operation was performed at the age of six (now only seven) months, was of the following extraordinary dimensions:—Round the forehead, and back part of the head 30 inches, and from ear to ear, across the vertex 24 inches; which measurements will be better understood by stating, that the larger circumference of the adult head averages but 22 inches and from ear to ear but 12; and of a healthy child of six months old the largest circumference averages 16, and from ear to ear 9 inches. The infant belonging to respectable parents, is under the immediate treatment of one of our surgeons, and is submitted to a novel practice, viz. the removal of the water by degrees, through means of operation, and at the same time the employment of pressure. The infant has undergone the operation five times, and 110 ounces (nearly seven pints) of water, have been removed. The present state of the infant and the effects of the operations and treatment are such as afford well-grounded hopes that for this disease, considered hitherto hopeless, a remedy has at length been found.—*Salisbury Journal.*

From the Massachusetts Agricultural Repository for
June 1823.

Some notice of Thomas Andrew Knight, Esq.
President of the Horticultural Society of London. His experiments and present to this Society.

BY THE CORRESPONDING SECRETARY.

If any apology could be necessary for the brief and imperfect notice which we are about to take of one of the most distinguished cultivators of the age, of a man who has done as much to enlarge the boundaries of theoretical agriculture, and horticulture, as any man living, while he has at the same time done more than any man with whom we are acquainted to advance that science *practically*, it will be found in the kind expressions of his regard for our country, and his generous exertions to make us partakers of the improvements he has actually effected in his *own*. To those who may be disposed to consider horticulture as less interesting and less within the province of this society, we would observe (at the hazard of repeating and reinforcing the remarks we made in our first article) that it is precisely the branch of agricultural industry which in our country needs the most attention. It is the one in which we are most deplorably deficient. So long as we were surrounded with Indian neighbors, and our crops were so precarious that our only anxiety was to procure bread corn sufficient for subsistence, it was natural that we should be indifferent to the rich profusions of vegetables and fruits, which nature has provided for our luxurious enjoyment. In this particular, we can without blushing, compare ourselves with the European nations at a period not far distant; and when we learn that the water-cress was the only salad for the royal table in the reign of Queen Elizabeth, we may not be surprised at the scanty supply of our own tables, fifty years since. But we are past that age, and we see no reason, why we should not have the finest melons of Persia which we can grow in the open air, while a Russian Prince will enjoy them in spite of nature, by expensive hot-houses heated by steam. We feel only a sentiment of humiliation, when we reflect, that countries which the sun never heats, produce the most luxurious fruits, while our sun wastes its powers in many parts of our country on a rich and productive soil, which is applied, in most cases, to the raising of the coarse vegetables, which our Indian predecessors bequeathed to us. In this remark we refer only to vegetables for the table, not to our invaluable staple articles.

Much has undoubtedly been done in the vicinity of our great towns, and horticulture has within our memory made a progress equal to our growth and improvement, but much remains to be done even here, and the inhabitants of the country at large may be considered as to horticulture, in a state of nature, excepting always some liberal, and spirited individuals who have made horticulture their study. After the provision for the support of life, come our comforts and rational luxuries, and if these can be obtained, without neglecting the more substantial and important articles, it is our interest to procure them. This is our apology for introducing the character, discoveries, and exertions of Mr. Knight. He has devoted his life to the investigation of the physiology of plants.

and it has been his rare merit, to submit his theories to the *best test*, that of experience. He no sooner settled a principle than he undertook to shew its truth by actual experiment, and to prove its importance, by applying it to the practical amelioration of horticulture. He early announced, that individual varieties of plants have their *limited age*; that although by culture, and in favorable circumstances, they may survive that age, they generally after that period decline and become weak, and of course unprofitable. With respect to the potatoe, he ascertained with as much precision as the nature of the subject will admit, that the specific varieties do not last in perfection more than fourteen years. No observing man in any country could doubt, as to the temporary duration of the varieties of this vegetable, however he might question the accuracy of the *precise limits assigned by Mr. Knight*. There is not a single variety of the potatoe now cultivated with us with which we were familiar thirty years since; and within twenty years, we have known several sorts which were invaluable, gradually run out; and this too, not from any want of attention, but from the impossibility of raising them. We will mention two sorts, as examples, the round cranberry potatoe, better than any now in market, a great bearer, excellent in the spring after other potatoes become flaccid and watery. We continued to raise them till they would not produce double the amount of the seed put in. They are now *extinct*. Another was a blue potatoe, with white spots—a delicious variety, brought from England direct, and also from Connecticut. For the last four years, it has become extinct. Some persons are deceived by appearances. We have always *white* potatoes, and they think them the same, but the varieties are infinite, and are constantly changing. The long reds, called the River Plate potatoes, have essentially changed their character, and ten years hence we shall no longer see that very valuable variety. So far our experience fully supports the theory of Mr. Knight.

Mr. Knight, if not the first to suggest the mode in which the sap circulates in vegetables, was, we are persuaded, the first who proved it to the satisfaction not only of men of science, but of the most incredulous and ignorant. Some of his early experiments were made on plants whose parts are transparent. He took, we believe, the Balsamine, or "Touch me not." He watered it with a colored fluid. He saw that the fluid passed up in the central parts of the plant, made its way into the leaves and having colored them, it returned by the bark which was the last affected. For the information of those who have not attended to the structure of plants, it may be remarked, that they consist of an external covering which is generally very thin, called the Cortex; of a softer substance, which is usually confounded with the other, called Liber; of a white portion, called by botanists, Albumen, and commonly known as "sap wood;" and the Heart-wood, which in more durable trees is usually much the more dense and solid. Mr. Knight maintained that the sap ascended in the Albumen and descended in the bark, or between the bark and Albumen, where it made its deposit of new wood. This theory was not without its *practical* value. It explained the reasons of the fact of the destruc-

tion of trees by decortication or a *too great removal of the bark, if accompanied with such wounds in the Albumen as to prevent the formation of new bark*. It was known before that you might cut off half the top and half the roots of a tree and it would still flourish, but if you should make a wound of one inch wide through the bark, and into the Albumen, the tree inevitably perished. His theory led to various experiments, founded upon its undoubted truth Mr. Williams, of Great Britain, applied it to the early maturation or ripening of grapes, by taking off the bark to the extent of a quarter of an inch in width; it was found that the sap was impeded in its descent, the parts above became larger, the fruit swelled and ripened *earlier and was more large and fine*. This experiment was repeated in this country by the writer of this article, and its success was so perfect, that nothing could be said against the theory by those who were eye witnesses of its most extraordinary effects. Another consequence followed from this discovery of Mr. Knight. If fruits can be hastened to maturity, and enlarged and improved by partial and prudent and judicious decortication, why, it was asked, may it not be applied to the bringing trees earlier into bearing, than by the ordinary process of nature? This it was said would necessarily be the effect of detaining the sap preternaturally in the branches, and thus forcing the plant to produce blossom buds instead of leaf or branch buds. It was before well known to gardeners, that any thing which checked the growth of a fruit tree, hastened the production of fruit. It was reserved for Mr. Knight to shew the *causes*, and to submit the whole process to rules as certain as are known in any other branch of natural science. In all, we are stopped at certain points, when we rashly venture to penetrate the great secrets of nature, but this is no reason why we should not search as far as we can find intelligible explanations and facts.

Perhaps it would be satisfactory to our readers to have experiments *at home* stated to them, in support of Mr. Knight's theories, and we trust that due credit will be given to our statement of *actual* experiments, especially as nothing would give us more pleasure than to afford any cultivator the most perfect satisfaction as to the accuracy of these statements, if he will do us the honor to call and examine the subjects of our experiments.

On two orange-trees from St. Michael's, which had never borne fruit, though we had them many years, we practised decortication, taking off a ring of the bark of half an inch in width. In the following spring, this year, the gardener expressed to me his surprise, that those limbs were literally covered with blossoms. He had not been in the secret. We pointed out to him the decortication or ringing, or as we say, the "girdling," and it was found, that while every other part of the tree was without blossoms, those which were operated upon were far *too greatly covered* with them. In this case we committed a mistake. The orange-tree puts forth only once in a year ordinarily in our climate, or under favorable circumstances, twice. Ringing or girdling should only be executed when the sap is in the greatest possible degree of action. These limbs are not healthy, and we fear will not hold their fruit, but the experiments shewed the principle in its

est light. The general rule is, to girdle the tree in its most rapid state of growth, to make the decortication or ring narrower according to the vigor of the tree, but so little in all cases as to enable the tree to close the wound during the same season.

We made a similar experiment on a flowering plant, the beautiful *Pastiflora Alata*, and drew it by this process into flower, at a time in which it never flowers in the ordinary course of nature, that is, in the month of June. Its usual time of flowering with us, is in March and April.

We proceeded to experiments out of the house, within the reach of all cultivators. We tried this plan on 20 young pear trees, some two and three branches—trees, which had been grafted from 10 to 12 years, without fruit. The spectacle on so extensive an experiment, is really interesting and instructive, showing the power of human art over nature. A single branch in a tree is at this hour, as we are writing, absolutely snowy white with flowers, while every other branch on the tree is as barren and unprolific, as it had been every preceding spring, when it had disappointed our hopes. We sported very much in our experiments. On some, trees we girdled only on others 2 to 5 branches, but the extent was so perfect, that before you reach the tree, you can decide precisely which were girdled. The same experiment was made on pears, with equal success.

As we here, however, check any disposition to have been excited in favor of this mode of hastening early bearing, by saying, Mr. Knight, from whose theory the experience has been derived, is opposed to it on a large scale. He thinks it will shorten the life of the trees subjected to it; that it is contrary to the course of nature, and is only just when you wish to be certain, whether the fruit you have bought or grafted are really such as you supposed they were, or when you have grafted fruits, to enable you to ascertain the ears earlier their qualities, in order to know whether you should reject them or not. I carry my apprehensions so far (I say it with great diffidence) as this learned cultivator. The effect of judicious girdling is nearly the same with grafting; that produces a similar incision of the sap, a callous is formed between the original stock and the graft, and yet we see the branches continue productive, and enjoy excellent health. No doubt great discretion and care should be exercised in the application. Mr. Knight has adopted other modes of hastening the early production of fruit on pear-trees. Some he raises in pots and boxes, and he bends down either to a horizontal, or to an anti-perpendicular form, if we may be allowed a novel expression. The sap is expedited in its course, and Mr. Knight has shown that the principle of gravitation is as operative in the fluids of vegetable life, as in the mineral. The effects are nearly the same as in girdling, producing earlier bearing.

These are but a part of Mr. Knight's labors and services. Following up the Linnæan theory of the sexual system of plants, (or to speak in more better adapted to all classes of readers,) proceeding upon the well established fact, that certain parts of the flower, called Anthers, produce a dust called Pollen, which is indispen-

sable to the fertilization of the germ or fruit, a fact known to be true, before Linnæus existed, but which never received perfect confidence, until he demonstrated it. Mr. Knight has devoted 35 years of his life to the practical application of this theory, which he has not only demonstrated by hundreds of experiments, but he may be said to have created many new and valuable varieties of fruits hitherto unknown. He has obtained new varieties of the pear, the apple, the grape, the plum, and the strawberry. He has demonstrated, that we can correct the defects of one variety of fruit by another, by introducing the farina of a pear for example, which has too much austerity or acidity, into the flour of another pear, which has too much sweetness, too insipid a sweet, you may give to the new product a taste and flavor, which may be perfectly agreeable. So it has been ascertained by Mr. Knight, that by the same process, a fruit which is defective in vigor, which bears with great reluctance in a cold climate, may, by intermixing it, or coupling it with another tree of the same species of a hardy character, acquire the vigorous constitution of one of its parents, and still retain the excellent qualities of the other parent. There is, indeed, no end to the changes which have been produced by Mr. Knight and others, not in fruits, but in flowers, by this process. We are aware, that this statement, to those who are ignorant of his exertions and success, may seem to be extravagant; but we can affirm, that he has done more to improve horticulture than any person of whom we, in this western world have any knowledge.

These remarks were intended as an introduction to a notice of the efforts which Mr. Knight has generously made to communicate to America some of his improved fruits. In 1822, I had occasion to write to Mr. Knight to procure the last numbers of the Horticultural Transactions, for the College; he replied to my letter in the most friendly manner, appeared to be highly gratified with opening an intercourse with our country, expressed his strong attachment to it, his disgust at the libels on our country in some of the presses of Great Britain, and his intention to send to us the best new fruits which the late improvements had introduced; declaring at the same time, that though he should confide them to my care, it was under the full belief and expectation, that I should disseminate them as extensively as possible. I need not say, that he could not have given me a charge more agreeable; and that without the smallest regard for personal interest, I shall circulate as rapidly as possible, by buds and scions, every variety of fruit he may send. I shall consider myself steward for the public—but I ought to remark, that as he sends but one individual specimen, the progress must be slow, and that I must exercise a discretion in giving scions and buds to such persons as will be most likely to take good care of them; but I shall do it in all cases on express condition, that the same freedom of circulation shall be practised by all.

I shall close this article by inserting Mr. Knight's last letter to me, accompanying certain fruit trees sent this spring—

"Downton Castle, Feb. 15, 1823.

"JOHN LOWELL, Esq.

"Dear Sir—I have this day sent to Messrs. Thornely, of Liverpool, to be forwarded to

you, a box containing trees and grafts of *ten* new varieties of pears, which here ripen in succession from October to May, and which I conclude in your warmer summer climate will ripen in succession—I could have sent a larger number of varieties, but those sent are the best and most productive, and inferior varieties that would ripen at the same seasons, I did not think worth sending. Each tree has a label and is also numbered besides, and I will now give you a concise description of each variety. I have also sent grafts of each variety from bearing trees, that you may certainly have each variety.

No. 1. Cassinot—A large pear, yellow upon one side and red upon the other, ripens in October.

No. 2. Tillington—This is described in the Horticultural Transactions. It is perfectly melting or rather perfectly beurree, and very rich, sprang from a seed of the autumn bergamot,—and the pollen of the Jargonelle, and its form is precisely such as you would expect from such a mixture. It is ripe in November."

[N. B. by the Corresponding Secretary.]—This example will shew our cultivators the process of Mr. Knight and the great changes produced by it. He removed from the flowers of the autumn Bergamot all the anthers. He impregnated the germ with the pollen of the Jargonelle. He took the seeds of the fruit, thus obtained, sowed them, and produced a new pear, having a mixed form, between that of the Jargonelle, which is long and eminently pear shaped—and that of the autumn Bergamot, which is flattened, and rather apple shaped—and it ripens nearly two months later than either of its parents. Being a new seedling, it will have strength and vigor and endure many years. Mr. Knight computes the longevity of a new variety of pear at more than 150 years. We may then form some judgment of the value of such an acquisition, when we know and have perceived for many years the gradual deterioration of the St. Germain, St. Michaels, Chaudmontelle, &c.)

"No. 3. Urbaniste—A large and nearly globular pear—color yellowish green—the flavor of rose water. Season, November.

"No. 4. Beurree Knox—Large, pear shaped, yellow. Season, November and December, an excellent pear.

"No. 5. Marie Louise—Middle sized—color, pale yellow. Season, November and December, a most excellent variety.

"No. 6. Napoleon—Somewhat smaller than the Marie Louise, exceedingly melting and juicy. Season, November and December.

"No. 7. Florelle—Middle size and pear shaped, color, bright red, nearly scarlet, with minute dark points, a most beautiful and excellent variety. Season, November.

"No. 8. Colmar d'Hyver—Shape varying from nearly globular to pear shaped, color, yellowish green. Season, January—a melting pear of first rate excellence and very productive.

"No. 9. Passe Colmar—Large and pear shaped, but very broad towards the eye. An exceedingly fine melting pear, which by being kept in different temperatures, may here be brought to table in perfection from the beginning of January to the middle or end of April. This variety is productive to a fault. I am generally obliged to take off 9-10ths of the fruit.

"No. 1. Hardenpont de Printems—A large pale green pear with rather a rough skin. It ripens *here* (in England) in the end of April or beginning of May—and its flesh at that period nearly resembles that of the Brown Beurré in Autumn. It is a very productive variety, and *in your climate* will I believe prove the most valuable variety of all.

"No. 11. Gilliflower apple—*Grafts only sent*—Form angular, flesh perfumed and remarkably yellow. It is in perfection in *winter and spring*. It would afford in a warmer climate a most excellent cider.

"No. 12. Sreency Nonpareil Apple—A very large variety of the Nonpareil, very excellent ripened on a south wall, or in a very warm season, and good situation, but too late for *our climate*. I believe it would suit yours. It is entirely new.

"No. 13. Black Eagle Cherry.

"No. 14. Elton Cherry.

"No. 15. Waterloo Cherry.

All these cherries are new varieties produced by Mr. Knight—they have been described in the horticultural transactions and colored plates of them given—they have all of them valuable properties.

It should be recollected, that Mr. Knight often fails in his numerous experiments, and it is only the excellent new variations which he presents to the public.

"No. 16. Downton Cherry—It is a white or pale red cherry with white flesh, and it is believed will prove an excellent variety.

No. 17. Cooes Golden drop plum—A fine variety from the original stock.

No. 18. A very large new plum of a green color, which promises well.

Mr. Knight added also two hundred Downton Strawberry plants; a new variety, but they perished in the passage.

The trees were admirably packed, and although they started more than could have been desired on the passage, yet there is no doubt we shall save every variety except perhaps one or two of the cherries—but had they all perished, our feelings towards Mr. Knight would not have been affected. His good intentions—his kindness towards our country, his philanthropy, would not have been the less. Unsolicited, he has bestowed upon us, what is of no small value, independent of the excellent intention. One new, and excellent variety of fruit is a great gain. Now have the St. Germain and St. Michaels Pear contributed to the pleasures of our tables? Who would not be pleased to have *ten new and excellent varieties* of pears, in the prime of youth, to supply the place of those, which we must soon lose? We trust we shall find some apologists for the zeal with which this article is written. There is something so kind, in this intercommunication between cultivators of different countries; it seems to be such a forgetting of the old circumstances of separation, that one cannot but be pleased with it.

* So named I have observed from Monsr. Hardenpont of Mons in Brabant, who raised it as a seedling. It is cherished by the French Gardeners Beurre. Kauer, but the English cultivators give credit to its creator, or raiser.—*Cur. Soc.*

To the Editor of the New England Farmer.

SIR,—In your paper of the 14th inst. you have copied an article from the Boston Recorder, on

the subject of Lightning Rods, in which it is stated, "The whole expense of one rod, for a two story building, including the silvering the points, will not exceed \$50." I would inform the public, and especially my brother farmers, that I have lately erected a lightning rod on my house, which is two stories high, and the whole cost was as follows, viz.

Paid for 65 lbs. rod at 8 cents,	5 20
" " silvering four points,	1 25
" " putting up rod,	1 25
	<hr/> \$7 75

Yours, &c.

BROOKLINE.

Oct. 10, 1823.

TO THE EDITOR OF THE NEW ENGLAND FARMER.

Frankfort, (Me.) Oct. 6, 1823.

SIR,

I notice that you are writing on the "Slaving of Horses." It has been a dry season here, and we have had no slaving among the horses. If horses here were afflicted with it, I would put two into a stable, and keep them there until they became both dry and hungry. I would then let one drink all the water he would, and turn both into luxuriant feed, where there was no water. I think they would not slaver in the same proportion. It is my opinion that the slaver is no more than the running off from the stomach of redundant water, where horses feed on very succulent grass. Let a horse, if he slavers, eat dry hay, if he will, and not drink. I presume it will stop the slavers, by taking up the redundant water.

I am, Sir, yours, very respectfully,

ARCHIBALD JONES.

REMARKS BY THE EDITOR.

We are under great obligations to Mr. Jones for the above communication, but do not perfectly coincide with him in the opinion that "the slaver is *nothing* more than the running off from the stomach of redundant water, when horses are fed with succulent grass." Although that cause may, perhaps, occasionally produce running of water at the mouth, we are confident that "succulent grass" is not the *only*, nor the common cause of the slavers. Our opinion is founded on the following facts:—

Mr. Peters, a very respectable practical farmer, of Westborough, Mass. in his communication, published p. 53, of the 2d vol. of the New England Farmer, expressly attributes the slavers to "a kind of grass of second growth, making its appearance the fore part of July, much resembling oats." He likewise says, this grass, "when chewed, causes a flow of water in the month more than any other vegetable that I have ever seen." And it appears from Mr. Peters' statement that the disorder was not known on his farm or in his neighborhood, 20 or 25 years ago, before that kind of grass, to which he attributes the slavers, had made its appearance.

Dr. Abraham Perlee, of Wilmington, Delaware, produces what appears to us conclusive evidence, that a certain plant which is called *Sprague* (*Euphorbia Maculata*) will cause this disorder. His testimony is given, p. 70, of the 2d vol. of the New England Farmer, and we shall repeat but one short sentence. "When the

horse was perfectly free from ptyalism, [slavers] a considerable quantity of clover carefully gathered without the Euphorbia was given him, and no such effect was produced." Likewise appears by the same statement that a small quantity of clover or any other grass, given with Euphorbia, invariably produced slave. Now if the plant, mentioned by Mr. Pet would salivate a man, it would probably produce a similar effect on a horse; and if a considerable quantity of clover without Euphorbia would not produce salivation, but a "small quantity" with Euphorbia never failed to produce it, complaint, we have good reason for believing that Euphorbia was the cause of the mischief. Perhaps "succulent grass" alone in great quantity, may produce a running of water from the stomach of a horse, but if so, it does not prove that the slavers is *nothing* more than such a flow of water. Warm water taken by a human subject, in sufficient quantity will be rejected from the stomach, yet we do not consider water to be an emetic. Besides, we have seen horses afflicted with slavers in a dry season and in short pastures. We are not, however, positive that are right or tenacious of our opinion. This is our only object, and we should ever be obliged to Mr. Jones or any other gentleman who may suppose us to be in an error, for attempt to point out our mistakes, and any libelation of the reasons on which his dissent is founded.

NEW ENGLAND FARMER.

SATURDAY, OCTOBER 18, 1823.

BRIGHTON FAIR, &c.

Massachusetts Agricultural Society's Annual Cattle Show and Exhibition of Manufactures at Brighton on the 15th and 16th inst.

The Show was, on the whole, as good, and in many respects, better than any preceding one. As to the bull calves, it was decidedly superior, and in articles of substantial, and fancy home made manufactures it was far before any former exhibition. The usual dress was omitted, for the reasons assigned by the President, Mr. LOWELL, who introduced the proceeding the day, upon his first taking the chair, with the following remarks:—

"In first entering upon the public performance of duties of this arduous and highly responsible of which has been successively held by Russell, Stone, Adams, Dexter, and my lamented Parent, it would indeed, strange, if I did not feel more than ordinary emotion, and a deep sense of my own inferiority to predecessors. The only assurance I can give to the numerous members of this ancient and important society, that I shall endeavor by zeal and activity in every degree to supply my deficiencies in knowledge and ability.

"The address upon some agricultural topic which has been for several years past delivered on this occasion having been found to interfere with the constantly increasing duties and labors of the trustees, and the respectable citizens, who have liberally afforded their aid in the distribution of our premiums, the Trustees have deemed it expedient to omit it for the present. There is indeed less occasion for them now than at early periods of this annual exhibition. County societies have sprung up in almost all parts of the state, men of talents and learning, in every quarter are

themselves to the dissemination of agricultural information. Several journals are now published in its parts of the United States, placing this hitherto neglected science and art in some degree on a footing with its sister arts. Newspapers are now supported in Maryland, New York and Massachusetts, exclusively devoted to the interests of agriculture, and our citizens are to feel that it is as interesting, though painful in consequence to learn that a night frost has cut off one hundred dollars worth of crops in Maryland, or that a fire has overwhelmed one hundred thousand dollars merchant's hopes, or a fire has consumed a like amount of the labors and property of the manufacturer. Those who wish to read, therefore, may resort to agricultural journals and newspapers, and we may sincerely devote this day to the business, in which, the hopes, the pride, the just and laudable attention of agricultural friends are principally concerned. Arrangement will be much more convenient to permitting them more time to attend to the objects having patriotically exhibited. Though we shall the Address, we would by no means neglect the noble custom of our pious ancestors, of invoking the blessings of the Almighty Ruler of the Universe over our proceedings, our country, and our efforts to the means of agricultural improvement.

On any occasion, of a character not purely religious supplications, to the Supreme Being are, surely they will be admitted to be so, when at the moment of harvest we are assembled to exhibit the fruits of divine bounty from the orchard and from the field, from the fold and from the stall. *On him alone we must be on such an occasion perfectly sensible, that all these blessings directly flow, that to him, we owe, that intelligence which enables us to improve what his bounty gave—and the civil privileges, and institutions, which permit us to them in greater security, than any people on earth have ever done since the expulsion of our parents from the garden of Eden, to this day of multiplied light and knowledge—may we never, however, forget, that the original condition upon which these gifts were bestowed, was, that we should use our endeavors to extend and improve them.*

Full account of this show, of its awards, and the names of the several committees will be published in our next number.—The committees had not time to send in their reports for publication and the sentiments of the festival were not duly arranged and we could not delay the publication of them till we could assure that they are perfectly correct.

COMMUNICATION.

AGRICULTURAL PRODUCTS EXHIBED AT BRIGHTON.

Several articles were sent to the Agricultural Hall for gratification of the curious in the uncommon productions of nature. A Sicilian squash, raised on the farm of Mr. Isaac Cook, of Brookline, measuring round the middle three feet in length. Several of the Sugar corn very large size, very productive and most valuable stock, from the farm of John Prince, Esq.—A variety of the Mangel Wurtzel from Mr. Prince and another one from Gen. Sumner, raised in a seedling plot of the seed planted the first day of July, measured 11 1/4 pounds, and measured 23 inches in circumference; a few very large pippins. A pear from the farm weighing 23 1/4 ounces. A basket of pears, raised and brought to America by Gov. Endicott. Many more and full ears of the very productive corn of Essex, raised by Mr. Prince, the largest ear exceeding sixteen inches in length. A most productive vine of a grape vine, with the fruit on it, from the farm of Mr. Cook, of Brookline. A variety of the small mill quality, raised by Mr. Prince, from Tripoli. Four trees, bearing large apples on

them from the nursery of Deacon Lealand, of Shattuck. The wines for exhibition and premiums, were valuable, as the luxury of imported wines is one of great cost. The wine from Mr. Prince, of three years old, made of currants, was in imitation of the flavor and taste of a favorite French wine, and may become valuable as a substitute. The wines from the Messrs. Kenricks, of Newton, made also of the currant. Wine more like a rich cordial, which may esteem a pleasant liquor. Wine also from the elder berry, from Mr. Spencer, of Beverly, was sweet and pleasant, and reputed very wholesome. This attention of gentlemen in sending rare productions from their farms and gardens, serves the double purpose of exciting emulation by good example when the production is of a common kind, but of uncommon excellence, and that of saving labor to be better bestowed when the production is of an uncommon kind, but not of an uncommon excellence, and may both serve as an attraction to the show, and a gratification to the observing and the curious. B.

Information respecting the culture of the Grape Vine.—A friend to our establishment requests information through the medium of the *New England Farmer*, relative to the cultivation of the *Grape Vine*, both native and foreign; and particularly the best means of preserving the latter through the winter, in our climate. Any communication on this subject from an experienced and scientific cultivator, would be thankfully received by the Editor, and would doubtless prove beneficial to the public.

Officers of the Middlesex Agricultural Society.

The following gentlemen were chosen officers of the Middlesex Agricultural Society, at their last meeting, for the year ensuing:—Col. Joseph Valentine, of Hopkinton, President; Rufus Homer, Esq. of Stow, Vice President; Benjamin Dix, Esq. of Littleton, 2d Vice President; Nathan Brooks, Esq. of Concord, Recording Secretary; Josiah Adams, Esq. of Framingham, Corresponding Secretary; Col. Daniel Shattuck, of Concord, Treasurer.—*Middlesex Observer.*

A letter from an officer of the Constitution, dated Gibraltar Bay, Aug. 26th, says, "The events of Spain have lately been the most unpromising kind. A universal defection has been spread through all classes of military and civil society in that devoted country. French gold has superseded the necessity of French arms."

Latest from Key West.—The U. S. schooner Allen, Legare, arrived at Savannah on the 1st inst. in 11 days from Key West, bound to Washington. Commodore Porter was nearly well, and had left that place in the Sea Gull for Norfolk. The squadron except a guard of marines, had all been ordered to sea, in consequence of increasing sickness. Several additional deaths had occurred, but no names are mentioned.

The treaty between the Florida Indians and the United States was signed at the encampment near St. Augustine, on the 9th ult. The particular object of the treaty is not stated in the St. Augustine paper. We understand, however, that the Indians have agreed to abandon those fine sections of country on the Micassee, Tallapoosa, and Alacua, which they now occupy, and locate themselves between Tampa Bay and Charlotte Harbor. These lands are said to be among the most valuable in the territory—the soil being equally adapted to the culture of Sugar Cane, Corn or Sea Island Cotton, and as it is expected that the seat of government will be located in their vicinity, it affords a fine opening to an industrious population.

Savannah Rep.

Fire.—During a smart shower of rain last evening, accompanied with high wind and very violent thunder and lightning, the bells gave the alarm of fire, which for a few minutes assumed a threatening appearance. It proved to be the barn of Mr. John B. Lord, Belleville. We understand it was struck by lightning, and containing a considerable quantity of hay and other combustibles, was in an instant wrung in flames, and with its contents burnt to the ground.

Newburyport Herald, 4th inst.

Agricultural Report for September.—District of Quebec.—The weather this month has been dry, with the exception of some heavy rains about the middle of the month. On the night of the 21st, there was a frost, which continued every night throughout the week and completely destroyed all tender fruit, apples, and covered the forests with the brilliant furs of autumn, earlier than usual.—*Gazette.*

ALDERNEY BULL FOR SALE.

A very fine full blood ALDERNEY BULL, which was presented to the Massachusetts Society for promoting Agriculture by John Hubbard, Esq. This breed is considered in England, as superior for the richness of their milk, making considerable more butter from the same quantity of milk, than any other breed. He is now two years and three months old, is in fine health, and a gentle animal, and may be seen at the farm of John Prince, Esq. Jamaica Plain, Roxbury. For terms of sale, which will be very liberal, apply to JOHN LOWELL, Esq. or said Prince, in Roxbury.

If the above animal is not previously disposed of, he will be at the Public Show at Brighton, on THURSDAY 16th October, at 12 o'clock.

Roxbury 30th Sept. 1823.

JOB PRINTING

At short notice and fair prices, at the *Farmer's Office.*

The following lines from the Albany Plough Boy, rival the sweetest strains of Shenstone or of Akenside. Like those writers, all Mr. Southwick's effusions breathe the same openness of heart, the same abhorrence of duplicity and exalted love of virtue.— *Rochester Telegraph.*

TO A COUNTRY GIRL,
WHO EXPRESSED A WISH TO LEAD A TOWN LIFE.

BY S. SOUTHWICK.

Sweet Mary, sigh not for the town,
Where vice and folly reign—
Spurn not the humble homespun gown
That suits the rural plain.
In ev'ry street the city's glare
Doth simple hearts betray,
And simple hearts who wander there
Are sure to lose their way.
The tradesman plays his party pait,
To take the stranger in—
The profligate displays his art,
The modest maid to win—
He lures her to perdition's brink
By every treacherous scheme,
Then leaves the hapless wretch to sink
In pleasure's guilty stream!
The flaunting crowd, that seem so gay,
May please you for a while—
But joy with these doth rarely stay,
Or sweet contentment's smile.
The splendid dome that proudly rears
Its gilded roof on high,
Full oft conceals pale envy's tears
And disappointment's sigh.
There foul ambition loves to dwell,
False pride and lust of fame—
There malice and revenge rebel
Against the good man's name.
Ah! little do you know, sweet maid
What are the city spoils,
Where villains ply the canting trade,
And fraud is drest in smiles.
Then Mary sigh no more to rove,
Or change your native fields,
The rural walk, the verdant grove,
For all the city yields.
And when some swain, of soul sincere,
Shall seek your love to gain,
Trust to his faith nor never fear
That you shall trust in vain.
So shall your rustic life be spent,
With every blessing crowned—
Within your doors shall sweet content
And faithful love be found.
And when your infant offspring rise,
A mother's smile to greet,
The joy that sparkles in their eyes,
Shall your own bliss complete!
Your tide of life, thus even flowing
Will ebb at last, 'tis true—
When calm with hope your bosom glowing
You'll bid the world adieu!

[From the Albany Daily Advertiser.]

The grand epoch of mingling the waters, destined by nature, to swell the volume of the most magnificent river of the north, with those of the Hudson, is announced for the 8th instant, and some interest is excited to devise an appropriate mode of celebrating that auspicious event.

The river gods, the naiades, and the nymphs of the heathen mythology, whose exhaustless

urns and sylvan sports crewlike animated the pageants of Europe, afford abundant resources for display on this memorable occasion—but they are not perfectly congenial with the general habits, turns of thinking, and tastes, prevalent in this new world; and the American classic ground is certainly of a formation too recent, to be filled by imaginary, incomprehensible beings, of a grade superior in intellect and powers to humanity, emerging from a dense looming medium, tinged with the ignorance and credulity of the dark ages—for the origin of the congregated Americans of European extraction, is luminous as the glare of day.

Our Aborigines have their presiding genii, manitoes and spirits, hovering over every fountain, river and lake, of their country, whose malignity they deprecate, but whose beneficence they never implore; and from this, by a combination of comparatively, ancients and moderns, indigenous and local, perhaps a sufficient number of dramatic personages might be ushered on the stage, with an unique, but certainly a novel effect.

For example, *Skipper Hendrick Hulson*, an anglo-Dutchman, in his four-fold hosen and doublet, on the quarter deck of the sloop *Half-Aloon*, the Dutch flag, with the admonitory motto, *Fendragt macht macht*, waving over her head, a telescope in one hand, the other supporting a speaking trumpet, vociferating defiance to all intruders on his peculiar domain, to contaminate his ever-moving water with those stagnated in reservoirs, with which he never formed a wish to be connected.

The spirits of the Seneca, Cayuga, Onondaga and Skanetelas lakes, personified by Indian Chiefs, as hunters, in their gala costumes, painted, crested with the beads, beaks, or plumage of native birds, armed with spears, war clubs, bows, arrows and quivers, smoking the calumet and shaking their rattle traps, in bark canoes, laden with furs, peltries, skins, and beaver and Buffalo robes.

Citizens of the western regions, in canal boats, freighted with hemp, flax, wool, cordage, sailcloth, woollen and linen fabrics, plaster, salt, fossil, coal, wheat, rye, corn, barley, oats, flour, meal, smoked, pickled and dried fish, beef and pork, pot ashes, lumber, copper, iron, hardware, marble, mill and grind-stones, and innumerable other productions of their wide-spread country, all uniting in request to Skipper Hendrick to be admitted a free intercourse with his great arm of the ocean, to pass to the markets of the world, and to contribute to the lucrative trade of the commercial emporium of his favorite river, accompanied with the assurance, that the inhabitants on the great inland seas and the rivers flowing into them, are prepared to follow in their track, with the cotton, rice, indigo, tobacco, oil and sugar, and other valuable productions of the south.

The venerated *Columbus*, conspicuously stationed on another sloop, firm and erect, bearing a chain wrapped round his left arm, (a memorial of the gratitude of princes,) holding a map of the ample territories which his intelligence and perseverance have bestowed on civilized men—an astrolabe—sounding-line, entwined with sea-weeds, compass and his highly celebrated cask at his feet, his right hand pointing to the canal and ejaculating—*this is in the scope of my own creation*—on the forecastle, *Amigo*

Vespucci, in the garb of a petty officer, depicting the success of his injustice, in usurping the honor of imposing his name on this distinguished portion of the globe, so appropriately do to the greatest human benefactor of his race the great *Columbus*.

In this effort, more than one of the unities the drama must be grossly violated—but snatch a grace beyond the reach of art, and harmonize every discordance, an assemblage of American belles, in a galley, with a band playing some of our most admired national melodies under a standard inscribed *Vivue our friend*, a *Providence our guide*, would eclipse the meretricious or factitious splendors of either the ancient or modern bark of Cleopatra.

A dramatic writer may extract pageant from such materials, as fascinating as if a whole olympian group aided the witchery the exhibition. AN ALBANIAN.

MOUSE TREAD-MILL.

To the Editor of the Edinburgh Star.

Sir.—Having seen a paragraph in your paper some time ago stating that a gentleman in Kildale has trained two mice, and invented a machinery for enabling them to spin cotton yarn making 5d per day profit. I take the liberty of informing you that a Mr. Hutton of this town has had two mice constantly employed in making of sewing thread for upwards of months; and that the curious may be entertained with a fair statement of facts, I hope I will give place to the following description which is by no means exaggerated, thorough and understand the amusing operation.—The mouse tread-mill is so constructed, that the common house mouse is enabled to make attendance society for past offences, by twisting, twining and reeling from 100 to 120 threads per (Sunday not excepted,) of the same length, quality with the enclosed hank, which I send a specimen of their work for the inspection the curious. To complete their task the pedestrian has to run ten miles and a half. An ordinary mouse weighs only half an ounce. A half-penny worth of oat meal, at 15d. a peck, serves one of these tread wheel culprits. This journey it performs with ease every day for the long period of five weeks. In that time makes (110 threads per day, being the average 3,350 threads of 25 inches, which is very nearly nine lengths of the standard reel. A penny is paid here to women for every cut made the ordinary way. At this rate a mouse can 9d every five weeks, which is just one farthing per day, or 7s 8d per annum. Take 9d off board, and allow it for machinery there will arise 6s. of profit from every mouse year. The last time I was in company with the mouse employer, he told me that he was going to make application to the heritors for a lease of an old empty house here, the dimensions of which are 100 feet by 50, and 50 in height, which at a moderate calculation, will hold a thousand mouse mills, sufficient room being for keepers and some hundred spectators. I am allowing 200l. for rent and task masters, and 60 for the interest of 10,000l. to erect machinery; there will be a balance of 2,300l. per annum. This, Sir, you will say, is projecting with vengeance, but it would surely be preferable the old South Sea speculation. I remain your obedient servant, A CONSTANT READER.

NEW ENGLAND FARMER.

PUBLISHED BY THOMAS W. SHEPARD, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

Vol. II.

BOSTON, SATURDAY, OCTOBER 25, 1823.

No. 13.

REPORTS of the Committees of the Massachusetts Agricultural Society, as to the premiums awarded at the Cattle Show and exhibition of manufactures, held at Brighton, on Wednesday and Thursday, the 15th and 16th of October, 1823.

First Committee, on Fat Oxen, Bulls, and bulls. The President, assisted by Hezekiah Jos. Esq. of Marlborough, and — Perry,

Chairman of the Committee on certain donations of Live Stock, I am about to report decisions of that Committee, and to award premiums to the successful competitors.

Before doing it, however, I hope I may be allowed with some prefatory remarks. They be as short as I can make them, because I have the impatience of those who hope to find they are among the fortunate, and I have the vanity to believe, that I have the power to instruct or entertain you—that what I say, will be directed solely to the object of conciling those who may be disappointed, only in the awards of this Committee, but not of all my brethren, and their assistants.

I would not do to compare this exhibition to any, for that would imply the absence of skill, and judgment, and anxiety to do right; in this case, every expedient has been used to secure competent skill, to exercise the sound judgment, and with the deepest desire to give a just and impartial decision. We have the most experienced judges of animals—above temptation, or bias. They understand his laborious and unthankful office, with the hope, or the wish, of any other reward, but the promotion of the public good. We have the best farmers as judges of working and ploughing. We seek out the ablest and most skillful mechanics, (need I name them as Mr. Moody, of Waltham, and Mr. — of South Boston?) to judge of new inventions—we invite experienced importers or dealers of manufactured goods, to examine the merits and constantly increasing articles, which with ingenuity and taste of a country, preeminent distinguished for its inventive powers in the science and taste, the country of England of a greater name, of Perkins, are condescending to the common stock.

It could seem, then, that we have done everything in our power to secure intelligent and impartial awards—yet it must be seen and felt by every one, that in one respect, and in one only, a cattle show resembles a lottery—the intent of resemblance is, that as in a lottery, in these exhibitions, there are many blanks, and few prizes—and would any fair man, and interested friend to agriculture and manufactures wish it to be otherwise? Would it be just, that all should draw prizes? There would be an end at once to all competition—there would be no reward to those, who by patient, and cultivated ingenuity, had reared superior animals, or produced a fabric of superior beauty and durability. The very intent of a show is to discriminate and reward super-

rior exertions, and to encourage those who have come a little short of the prize, this year, to make their utmost efforts to excel in another. It cannot be too often repeated, that the task of judging is as delicate, as it is laborious and unthankful. It is unthankful, because the disappointed much outnumber the successful candidates. It is also unthankful, because the committees may occasionally (though not often) differ from the public opinion—yet an intelligent and impartial public, and a fair and generous competitor will admit the serious difficulties in the case, and that it is scarcely possible, that all men will think alike as to the beauty of an animal, any more than they agree in the relative beauty of their wives and children,—neither will they be more likely to agree in the other qualities of the animals, their aptitude for labor, their disposition to fatten—and still less, can uniformity of opinion be expected in the varied and ever changing forms, so arbitrary as in fancy articles of manufacture.

Having made these general remarks, applicable to all my friends and associates,—I will add one or two peculiarly adapted to my own branch of inquiry and decision.

As to fat cattle, there can be little difference of opinion. The animal has then run through his course—has performed his destined, and faithful and invaluable labors, to man, and by a hard, but inevitable fate, he is to be submitted to the knife, and the sinews and muscles which turned the sod, are to be converted into the sustenance of man. He is, when so fattened, in his most perfect state, and skillful men (such as I have had the pleasure to be associated with, can then decide, which animal is, on the whole, the best. They can do this with so much accuracy, that they can lay the ox (as the phrase is) within a score of pounds of his actual weight, and they can even decide in most cases the quantity of fat, or tallow, which will be found in parts concealed from the eye.

Not so as to the bull. In judging of a bull, many properties, or qualities, are to be taken into the estimate—his carriage, whether erect or groveling—his temper, whether ferocious or tractable—his eye, whether full or sunken—his neck and head, whether thin and delicate, or thick and fleshy—his coat, whether coarse, like that of a buffalo, or fine like that of a full blooded racer—his limbs, whether stubbed and thick, like those of an elephant, or delicate, denoting activity and power, like those of an antelope—his forehead and chest, whether deep and powerful, indicating that he will produce a progeny calculated to tear up the stiffest soil, and to remove the heaviest rocks—and a hind quarter, fitted with muscles, which, when properly loaded with fat, will furnish an abundance of delicious food. There are many minor properties, such as the straitness, and breadth of the back, and the elevated insertion of the tail, known to good judges, which I forbear to notice.

But my enumeration will satisfy any reasonable mind, that it is not size alone which can determine the preference, and that it is no light or trifling task to decide upon the properties

of that noble animal, the bull—the parent, and the most important parent, of our most valuable domestic animal. I would not be misunderstood, when I call him the most important parent, I mean it simply in this sense—while one cow can only transmit either her good or bad qualities to eight or ten individuals, a good or bad bull, may convey his good or bad propensities, to some hundreds.

The remarks I have made as to bulls, are equally applicable to bull calves, with one exception, which I beg every intelligent farmer to weigh. Bull calves are imperfect animals in a state of growth, often preternatural growth—as in man, we find children, often disproportioned, when growing, and at mature age of the most perfect proportions; so bull calves of little promise, often become perfect specimens of their species, and the most perfect calves, when young, not unfrequently prove distorted, or coarse or ordinary, when arrived at maturity. I treat your patience for these details, which seemed to me, however, necessary.

We award the first premium for a fat ox, to Asa Pond, of Peterham—weight 2597 pounds, \$30
The second premium for a fat ox, to Samuel Bowen, of Adams, in Berkshire, 25
The third premium for a fat ox, to Amos Davis, of Groton—weight 2260, 15
The first premium for bulls, to Col. Jaques, of Charlestown, for his red bull, called Middlesex, out of Cælebs, owned by him, 30
The second premium to Samuel Keir, of Charlestown, for his calf out of Boldness, owned by Jeremiah Parsons, Esq. of Woburn, and much improved in that part of Worcester, 20
The third premium to Col. Jaques, of Charlestown, for his bull out of Cælebs, called "Yankee," 10
The first premium for bull calves, we award to Jacob Sawyer, of Westminister, for a native bull calf of a breed that has often gained our premiums, weighing at 7 months old, 725 pounds, 15
The second premium for bull calves is awarded to John Brown, of Dudley, for a bull calf of the Holderness breed, 10
The third premium for bull calves is awarded to Silas Stone, of Sherburne, Middlesex, for a calf out of Fill-pail's pregnancy, owned by Mr. Alner Wheeler—Note, Fill-pail was presented to the Society by Col. Thordike, and imported from the Netherlands. His pregnancy in the third degree inherit fully his qualities, 5

There were several other fine bull calves, among which I am requested by the committee to notice that of Nathan Nichols, of Malden, out of Cælebs; that of William Dodge, and that of Daniel Stephens, of Marlborough.

Among many excellent bulls not included in the premiums, were a bull from Denton, by the Hon. Mr. Welles; Jupiter, a white bull, of Col. Jaques—The bull of Henry Rice, Esq. of the same breed, and a native bull, exhibited by David Perham

It will be seen by this enumeration, that even the second and third crosses, from the imported bulls, have carried the premiums, and yet it was not in any degree owing to any influence which I, as a trustee, exerted over two very respectable citizens from the interior—I am only the organ to communicate their opinion, carefully formed, and cautiously expressed. It will, however, be seen, that some native bull calves, of a superior stock, carried the two first premi-

um—a proof that we need selection and care only, to make our own breed equal to any we could import. Yet we must rejoice at the opportunity we have had to cross our breed with the most improved of foreign countries. If no other effect should be produced, than that of exciting attention to the improvement of our native stock, all the care and expense hitherto bestowed would be only as the chaff is to the plump and healthy grain.

JOHN LOWELL, *Chairman.*

N. B. There was a cow exhibited, owned by Charles Vaughan, Esq. of Hallowell, which for several accounts, did not come within the list of our premiums.—Yet it would be improper not to notice her—she was from an imported breed, of great value, and she was without question one of the most perfect animals ever exhibited in Brighton.

REPORT No. II.

The Committee on Milch Cows, Heifers, Sheep and Swine, consisting of E. Hersh Derby, Esq. Willard Gay, Esq. of Dedham, and Abner Wheeler, Esq. of Framingham, report:

That there were three premiums offered for milch cows, for which there were twelve candidates, and after long deliberation they have awarded the premiums in the following manner—The 1st premium of \$30 to the Rev. John B. White of East Sudbury—2d do \$20 to the Rev. Samuel Capen, of South Boston—3d do 15 ds. to Henry Rice, of Boston, for the Duchess of Marlboro'.

Mr. White who received the first premium, furnishes the following statement under oath. His is a native cow, raised by Mr. Noah Smith of Sudbury, is nine years old, and came into his possession in the spring of 1821. She calved on the 28th of May, the calf was killed the 11th of July. She has furnished 156 lbs. 9 oz. of butter, besides furnishing the family with a supply of milk. Weight of one quart of her milk 2½ lbs. Weight of milk given in a day when the calf was a week old, besides what he would take, 35 lb. 3½ oz. Weight of milk when the calf was three weeks old 32 lbs. 13 oz. Weight of milk given on the day after the calf was killed 60 lbs. On the 27th of Sept. weight of milk given in one day, 38 lbs. 12 oz. 15 qts. 1 pt. On the 11th of Oct. 38 lb. 14 qts. 3 1-5 gills.—From this it appears that the mean weight of milk given by the cow from the time when the calf was killed to the present is 48 lbs. a day. It also appears that when the calf was killed she gave milk at the rate of a barrel of 32 gallons beer measure in 5 1-3 days, and that she now gives milk at the rate of a barrel in 8 days and 3-9 of a day.

Mr. Capen who received the second premium, stated under oath that his cow was raised by himself, is from a superior native cow and a bull of the Hon. John Welles's stock—is eight years old, calved the 2d May, since which she has furnished 202 lbs. of butter; her greatest quantity of milk has been about 16 quarts per day, of very rich quality.

Mr. Rice stated that his cow by Denton was three years old last February, she calved July 27; she has given from the 9th of August, to the 13th Oct. 65 days, 2181 lbs. milk, averaging 38 1-5 lbs. per day.

The Committee noticed with much pleasure two other very fine cows, one belonging to the Hon. John Welles, the other to Mr. Luke Fiske.

There were twenty four Heifers entered for premiums, and your Committee had only three premiums to award. Among so many very fine animals, they found it extremely difficult to decide, and regretted that no distinction had been made in the premiums between those which had calved and those which had not. But taking into view every circumstance, they have been induced to award the first premium of \$15 to Mr. Samuel Jaques of Charlestown, for his full blooded short horned heifer of 16 months.

The 2d premium of 10 ds. to Maj. Benjamin Wheeler of Framingham, for his part blooded heifer of 11 months old.

The 3d premium of 7 ds. to Col. Joseph Valentine of Hopkinton, for his native heifer of 17 months old.

The Committee were highly pleased with several other heifers, and regret that they could not award more premiums. They feel desirous of noticing in a particular manner the five heifers by Denton, owned by his Honor Levi Lincoln, of Worcester, also five heifers offered by the Hon. John Welles of Dorchester, 1 by John Pierce Esq. of Roxbury; 2 by Jacob Knapp Esq. of the same town; 1 by George L. Stearns, of Medford; 1 by Samuel Brooks of Brighton; 1 by the Rev. Lemuel Capen, of South Boston; 1 by Dr. Codman, of Dorchester, and two full blooded young heifers by Col. Samuel Jaques of Charlestown.

In deciding the premiums on Merino Sheep, they have been governed more by the fineness of the fleece on every part of the same, than by the size and appearance of the animal, and have therefore awarded

To Samuel Henshaw, of Boston, the first premium for the best Merino Ram,	\$15
To Samuel Jaques, of Charlestown, the 2d do.	10
To Samuel Henshaw, of Boston, the first premium for Merino Ewes,	20
To Samuel Jaques, of Charlestown, the 2d do.	10

There were several other lots of Merinoes, all of which the Committee thought very highly of, several of which were very much superior in size and appearance to the ones to which they have awarded the premiums, but the quality of their wool was not of such exquisite fineness throughout. There were no Merino or native wethers offered for premiums.—They were much gratified by the appearance of four long woolled sheep from the Netherlands, imported by Col. Jaques, who has made great exertions to introduce fine breeds of sheep into the country, but as the Society have not offered a premium for sheep of that kind, they could not award any.

The committee award for the best Boar, the 1st premium to Gorham Parsons, Esq. for his Cobbet and Wellington boar,	\$12
For the 2d best to Silas Dudley, of Sutton	8
For the 3d, to Francis Moore, of Brighton	5
For the best Sow, to Silas Dudley, of Sutton	12
For the 2d best, to Gorham Parsons, Esq. for his Leicester Sow	8
For the 3d, to S. W. Fomeroy, Esq. of Brighton	5
For the best store Pigs, to Josiah P. Kenney, of Roxbury, the 1st premium	10
For the 2d best, to Luke Fiske, of Waltham	5
For the best spayed Sows, four in number, to T. P. Mariani, of Concord	20

[Your committee were much pleased with the appearance of these animals. Mr. M. furnished them with a description in writing of his mode of operation.]

Mr. Parsons desires the committee to state that he relinquishes the premiums awarded to

him for his swine, having intended to enter them for exhibition only.

All which is respectfully submitted.

E. HERSH DERBY, *Chairman.*

REPORT No. III.

BRIGHTON, OCT. 16, 1823.

The Committee on Agricultural Inventions

Report:

That among the articles presented of this description, Safford's Straw Cutter, is, in their opinion entitled to the Society's premium, from its great simplicity as well as its effectual operation. The motion is communicated to the feeders directly by a double threaded iron screw, without bands or any complicated machinery. The knives are flat and oblong, and affixed to the radius of an iron wheel, and fixed and un-fixed, and regulated with the greatest ease. The whole expense of the machine is fifteen dollars. It is said that it will cut a bushel of straw in a minute; and the testimonials in its favor are of the most decisive character, given by persons well acquainted with the use of such machines, who certify that "it exceeds any other they have ever seen, for cheapness, simplicity, dispatch and durability." Your Committee therefore award to Mr. Safford the Society's premium of \$20.

A machine, called Jaquith's Threshing Machine, was presented for premium by the inventor. It is chiefly characterized by its being the application of the same wheels to the action of flails, which are fed by gear, or bands. The operation of the machine is very simple and effectual, and in the opinion of your Committee is the best, which has yet been presented, for mowed grain. Its expense is thirty-five dollars, when prepared for the hand, and seventy five dollars when prepared for the horse power. Your Committee deem it entitled, accordingly award a premium of \$20—the proprietor adducing certificates, to the satisfaction of the Chairman, that the machine has been used and approved by some practical farmer.

Walter James presented for premium, a Corn Shelling Machine, the principal component parts of which were a fluted cast iron cylinder hung under the segment of another fluted cast iron inverted cylinder. Without attempting further to particularize its conformation, your Committee deem it sufficient to state that it performed its operations well, and is in their opinion an useful machine. Your Committee do not however, deem it so decidedly, if at all superior to machines, for a similar purpose used in this vicinity, as to justify them in awarding any premium; although they deem it well adapted for its purpose.

A Shearing Machine, presented by John T. Cambridge, of Springfield, Vermont, the operation of which is chiefly characterized by the horizontal motion and sliding action of the knife, by which it differs from similar machines in common use in our manufactories. It is a machine extremely handsome in its structure, and performs its work well—but not coming under the head of agricultural implements, is not embraced within the sphere of the premiums, and the authority of the Society.

The same remark applies to a machine denominated "Jencks's Alleviator." This your Committee apprehend to be a very excellent

vention, and is very powerfully recommended by Dr. Warren, of Boston, and others, for the dressing of persons, whose limbs are fractured, while in bed, with great ease and safety. While our Committee consider it a machine of great practical utility in hospitals and sick chambers, they deem it not within the objects or power of this Society to award to it a premium.

Various agricultural machines were presented for exhibition only—among these your Committee particularly notice Mr. Pope's threshing machine, which on a former year obtained the Society's premium. It has been since improved, and now can thresh, as it is stated, with a good power and the assistance of three men, eight to ten bushels of grain per hour—enlarged, to the application of a horse power, will thresh per hour, from ten to fifteen bushels of wheat, and from fifteen to twenty of rye or oats.

Messrs. Lincoln Fearing & Co. also presented for exhibition a variety of agricultural implements, consisting of forks, ploughs, Eastman's new cutter, from Baltimore, and Curtis's churn, from Connecticut; all of them to be found in our excellent and extensive collection of agricultural implements in Boston, and all machines of different degrees of merit, the particulars of which your Committee did not deem themselves called upon to estimate. They cannot fail, however, to express their gratification at the particular exertions of Messrs. Lincoln Fearing & Co. as well as at the general evidence of the increasing attention of the community to implements tending to improve and lighten the labors of agriculture.

JOSIAH QUINCY,
CYRUS ALGER,
PAUL MOODY.

REPORT No. IV.

BRIGHTON, OCT. 16, 1833.

The Committee on Manufactures award

to James Shepherd & Co. of Northampton, for the best specimen of Broadcloth, \$20

to Elihu & Howard, of Oxford, for the next best, 15

to Thomas Dedman, of Templeton, for the best specimen of Woollen Cloth, of household manufac-

ture, 12

to George M. Barrett, of Concord, for the next

best, 8

to James Shepherd & Co. of Northampton, for the

best specimen of Cassimere, 12

to the Wolcott Woollen Manufacturing Company, of

Northampton, for the next best, 8

to Lincoln Burr, of Hingham, for a piece of Ker-

sey, 2d premium, 8

to Messrs. Pomroy & Clapp, of Pittsfield, for the

best specimen of Satinets, 8

to Beth Bemis & Co. of Watertown, for the next

best, 5

to Mrs. Stephen Fay, of New Braintree, for the

best specimen of household Flannel, 10

to Jonathan Wilder, of Sterling, for the next best,

to Ephraim Coburn, of Dracut, for the best spec-

imen of Linen Diaper, 7

to Eideon Delano, of New Braintree, for a piece

of Linen Cloth, 3

to John Hunter, of New Braintree, for the best

specimen of Floor Carpeting, 15

to Joshua McVillie, of Concord, for the next

best, 7

to Benjamin Poor, of Newburyport, for the best

specimen of Stair Carpeting, 10

to Theodosia Converse, for a specimen of fine

blankets, 6

to Anna Buckman, of Tewksbury, for a specimen

of Linen Diaper Table Cloths, Worsted Stock-

ings and Work Basket (as a gratuity) 3

Also to Polly Leland for a piece of Cotton Diaper,

to P. Sanford and brother, of Medway, for a spec-

imen of fine Cotton Thread, 5

to Elizabeth Cowan, of Boston, for a specimen of

Thread Lace, 5

to Ann Heath, of Roxbury, for 13 pair of Cotton

Stockings, 3

to Mary Ann Plimpton, of Medfield, for a Straw

Bonnet, 3

to Olivia Stanley, of Dracut, for do, 4

to Eunice Barthol, of Newton, for two extra Fine

Straw Bonnets, 3

to Martha Daggood, of Shrewsbury, for a Bonnet, 3

to Lavina Sweet, of Foxboro, for a Bonnet made

from the husks of corn, 3

to M. W. R. of Boston, for a Cotton Counterpane

to Misses Baxters, of Quincy, for a Hearth Rug, 3

to Sarah Cushing, of Dorchester, for a Rug, 3

to Jane Coburn, of Dracut, for do, 2

to Betsey and Mary Monroe, of Lincoln, for two

Hearth Rugs, each, 2

to Caroline Cutting, of E. Sudbury, for do, 2

to Melitah Dean, of Mansfield, for do, 2

to Louisa Clark, of Boston, for do, 3

to Susanah Whiting, of Cambridge, for do, 3

to Anna Bemis, of Watertown, for do, 3

to Mary B. Converse, of New Braintree, for do, 2

to Mrs. Eliza Warren, of Leicester, for do, 2

to Catharine Pierson, for 3 pair of fine Worsted

Hose, 2

to Hannah Hawks, of Sterling, for do, 2

to Frances, Nancy, Elizabeth and Abel Wheeler,

of Worcester, for a specimen of Artificial Flowers,

exhibited as the work of young children, 2

each, 2

to John Thoreau & Co. for a specimen of Lead

Pencils, manufactured from Plumbago, native of

this country, 5

to Marian R. Haven, of Hopkinton, for 2 Straw

Bonnets and Calash of Straw, 4

to Sarah Pollock, of Canton, for a Grass Bonnet, 4

to Susan Whitney, of Dedham, for do, 4

to Abigail Goodale, of West Boylston, for wrought

Buttons and Frogs, 2

to Nancy Wheeler, of Worcester, for Tippets of

Turkey Down, 2

A Bonnet from Plymouth, made of white paper,

was considered by the Committee a curious

and ingenious article, but they doubted whether

it could be sufficiently serviceable to merit en-

couragement.

The number and amount of premiums on

Factory Goods having been diminished since

the last year, in favor of household fabrics, fac-

tory Flannels were not a subject of premium

the present year.

The best of the specimens sent for exhibition,

from the Amesbury Flannel manufactory, were

very fine and of excellent materials, and in all

respects well finished. There were pieces of

different qualities, but all creditable to the Com-

pany.

The Committee can say no less of the six

pieces exhibited by Mr. James Howorth from

his Factory at Andover.

The four pieces from the Salisbury Woollen

Manufactory were substantial goods, but not in a

finished style.

Many of the specimens of Household Industry,

exhibiting a commendable taste, ingenuity and

skill, are not rewarded by gratuities, not because

they were undeserving this distinction for any

deficiency in the qualities mentioned, but be-

cause it was necessary to put a limit somewhere

to this kind of reward—the Committee have

therefore conferred it on some of the most use-

ful articles only. Much praise, however, is due

to Miss Merrill, of Salisbury, for a parcel of

fine Linen Thread—to Hannah Edson, of Har-

wick, for Worsted Socks—to a Lady, of Ply-

mouth, for a Paper Bonnet—to T. P. Meriam, of

Concord, for a specimen of Stocking Yarn and a

pair of Socks—to Mrs. Robinson, of Worcester,

for Stockings and Socks, and to Mary Adams,

for a specimen of good Carpeting.

The pieces of Calico from the Charlestown

Bleachery (a recent establishment) were

thought by the Committee to be excellent

goods, and far preferable for durability to Eng-

lish calicoes of the same description.

A very fine Beaver Hat was exhibited by

Messrs. Dikeman & Shepard, of Northampton.

The Committee could conceive of no improve-

ment beyond it.

The case of Hats, from the Boston Manufac-

turing Company, were of the first quality of

gentleman's hats. This Company have in for-

mer years deserved and received the commen-

dation of the Committee on Manufactures,

whose favorable judgment has been confirmed

by the public. It is understood that the impor-

tation of men's hats, even of the best qualities,

is now very small.

The two parcels of S il Cloth, one by Mr.

George B. Chase, of Salem, the other by Mr.

George Johnson, of Cambridgeport, were pro-

nounced by competent judges to be without

fault, and these gentlemen have therefore se-

cured to themselves a good prospect of the pub-

lic patronage.

Four pieces of black Broadcloth, offered for

exhibition only by the Wolcott Woollen Man-

ufacturing Company, were very creditable to

the makers, and with a little more skill in the

finishing would have approached very nearly

to those which obtained the first premium.

The best of the Broadcloths, Cassimeres, and

Satinets, were much superior, in all respects,

to the same quality of goods exhibited at Eigh-

ton in any previous year.

RICHARD SULLIVAN, Chairman.

EDWARD TUCKERMAN,

JOHN LEMIST.

Important Discovery.—A man by the name of

Daniel Hawley, who has been a school teacher

in Carmel, N. Y. and its vicinity for about six-

teen years past, and established a good charac-

ter, has lately invented a new construction of

materials, which with the loadstone, will attract

and draw steel, and which will not continue,

but is immediately repelled the contrary way

and passes the load stone. Such an operation

by the magnet has always, by the great, been

considered to be impossible, which now may be

thought to be no more of a miracle than fiction.

As the operation has the appearance of a real

perpetual moving wheel, which, when finished,

it is thought can be applied effectually to boats

on canals, and for raising water, and to many

other advantageous machineries. Having seen

the operation on water, and not knowing why

it has not heretofore been carried into execution,

we are led to suspect that necessary means has,

in a great degree, prevented the inventor from

accomplishing his design in this great philosoph-

ical and important discovery; and were this

to be the case, we think that immediate as-

sistance should be rendered him, as we understand

that his earnings for many years past, have de-

frayed the expenses up to the present time. It

may be here observed, that he has invented some-

thing that will stop the force of attraction, which

surpasses the knowledge of all philosophical

discoveries.—N. Y. Spectator.

FRANCESTOWN CATTLE SHOW.

Report on Flannels, Blankets, Coverlets, Shawls, Hosiery, Bonnets, &c.

(Concluded from page 91.)

The committee appointed to award the premiums on Flannels, Coverlets, Shawls, Hosiery, Bonnets, &c. have attended to the duty assigned them, and after careful examination and comparison of the various articles, have awarded the premiums as follows, viz.

On Flannels.—No. 15, presented by Samuel Folsom of Deering, the first premium, of \$3; and to No. 106, presented by Mark Morse of Francestown, the second premium, of \$2. Both pieces were of a very superior fabric, and for fineness of thread and delicacy of touch, could hardly be surpassed; but Mr. Folsom's was the finest and received the first premium. A number of other pieces were presented which the committee consider entitled to great praise, particularly, No. 107, presented by Mr. Morse which was so nearly equal to his other piece that it was difficult to decide to which the premium should be awarded.—No. 64, presented by Kimball Emerson, and No. 63, presented by Thomas Eaton, and No. 51, presented by Joseph Philbrick, were of very superior manufacture, and the committee would have awarded premium to them had it been in their power. The committee are happy to observe the great improvement which has been made in the manufacture of this necessary article, and do not hesitate to say that a number of the above pieces were superior to any usually imported.

On Coverlets.—The first premium of \$3 to No. 53, presented by Mrs. Sabra Bailey of Weare, and the second premium of \$2 to No. 52, presented by Joseph Philbrick of Weare. Several other handsome Coverlets were presented, particularly one by Maria C. Ballard, of Henniker, all of which did credit to the ladies who manufactured them.

Fewer pieces of Linen were presented this year than the last. The committee presumed this must arise from a want of sufficient inducement to present, rather than decrease of the manufacture. The first premium, of \$4, was awarded to No. 55, presented by Mrs. Mary P. Darling, of Henniker. The second premium of three dollars, to No. 67, and the third, of two dollars, to No. 68, both presented by Samuel Chandler of Bedford. These were of the kind called table linen, of very fine even thread, and evinced a perfection in the manufacture of this article highly creditable to the county. The fourth premium, of one dollar was awarded to No. 22, presented by Simeon Walker. This was also table linen, and though not so fine and nice as the other pieces, was two yards wide.

The first premium, of two dollars for the best pair of knit Hosiery, was awarded to Mrs. Mary P. Darling of Henniker; they were of a fine linen thread and wrought in a very superior manner. The second premium, of one dollar, to Polly Starrett of Francestown—and the third to Humphrey Moore of Milford.

The first premium, of 4 dollars, on Grass Bonnets, was awarded to No. 77, manufactured by Miss Lucy Kimball, of Merrimack; and the second, of 3-dollars, to No. 78, manufactured by

Miss Sarah Kimball, of Merrimack; of these articles the committee can hardly speak in terms of too high commendation. No one can doubt the importance of this manufacture to the country, when it is considered that the article is now almost universally worn, and that large sums of money are annually sent to Europe for the purchase of it. If Bonnets as good or superior, can be manufactured in this country, the manufacture should be encouraged, and the committee do not hesitate to say that these Bonnets are as good, if not superior to any imported; and he who does not prefer American Grass Bonnets, wrought by the industrious hands of our fair country-women, to Leghorn Straw, has no legitimate claim to the name of *yankee*, and should be sent to Leghorn for a wife as well as bonnet.

The first premium, of 2 dollars, on Straw Bonnets, was awarded to Miss Susan Lord, of Francestown; and the second, of 1 dollar, to Miss Lucy Ann Fuller of Amherst. These Bonnets were neatly manufactured, and would discredit neither the fair hands nor the fair faces of the fairest of the fair, neither in making or wearing.

A number of articles were presented and referred to this committee, for which no premiums were offered. Many of these the committee have examined with much pleasure, and being allowed to appropriate a sum in discretionary premiums, have awarded it as follows:

To No. 91, being a hearth Rug, presented by Lucinda Gould, of Henniker, 2 dollars. To No. 12, a hearth Rug, presented by Benjamin Pettengill, of Salisbury, 1 dollar. To No. 85, a hearth Rug, presented by Humphrey Moore, of Milford, 1 dollar. To No. 20, a hearth Rug, presented by Peter Woodbury, of Francestown, 50 cents. To No. 71, a hearth Rug, presented by Sarah Kimball of Merrimack, 50 cents. To No. 93, a fine Cotton Handkerchief, presented by Sally Felt of Temple, 50 cents. To No. 31, an Indispensable, presented by Polly Starrett of Francestown, and made of small Glass Beads, 50 cents. To a Straw Indispensable, presented by Sarah Kimball of Merrimack, 50 cents. To No. 23, a Cape or Vandyke, wrought on Silk, with the down of Milkweed, presented by Sarah W. Livermore, of Wilton, 50 cents. To No. 13, being 5 Vest patterns, presented by Benjamin Pettengill, of Salisbury, 1 dollar. To No. 25, a Counterpane, presented by Melitable Beede, of Wilton, 2 dollars. To No. 18, a woollen Coverlet, presented by Peter Woodbury, of Francestown, 1 dollar. And to No. 65, a pair of Rose Blankets, presented by Samuel Chandler, of Bedford, 2 dollars. Also a number of pairs of Blankets, which were of a superior quality, particularly No. 66, presented by Samuel Chandler, of Bedford.

The committee would have been happy, had it been in their power, to have awarded premiums to each of the above, and other articles presented, and they can only regret that the industry and skill of the Society, in creating funds with which to reward, does not keep pace with the industry and skill of the Ladies in manufacturing.

All which is respectfully submitted,

JOSHUA DARLING,
ISAAC SPALDING,
JOHN DALTON,
for the Committee.

[From the Worcester Papers.]

On the 8th instant, the WORCESTER COUNTY AGRICULTURAL SOCIETY held their Fifth Annual Cattle Show, Ploughing Match, and Exhibition of Manufactures. Our account of the proceedings of the day must be condensed; and indeed minute detail is unnecessary. The reputation of these interesting anniversaries is now so generally diffused, and so firmly established, that they do not need any eulogiums to recommend them to public attention. It is enough to say that the present exhibition was decidedly superior to any that preceded it, and realized every expectation however sanguine.

The examination of Manufactures took place on Tuesday. The specimens offered for inspection occupied the convenient rooms with which the Society were accommodated by the kindness of Nathaniel Maccarty, Esq. The variety of articles, particularly of household manufacture, was greater than usual, and an improvement was visible both in the materials and the workmanship. We are happy to observe this increasing attention to so interesting a part of the exhibition, and we assure our enterprising Manufacturers and Mechanics, and our industrious housewives, that the members of the Society, and their fellow citizens at large, witness their exertions with the highest gratification, and most cordially wish them success.

The concourse of people assembled was very great, including many from a distance. His Excellency and suite gave additional interest to the proceedings of the day. The number of pens for animals was eighty-eight, all of which were well filled; and as many as fifty posts in addition were occupied by working oxen and steers. The number of animals was 371, of which 215 were neat cattle, and 159 sheep and swine. There were beside these a team of six yokes from Shrewsbury. All the arrangements of the day were regularly executed.

Twelve teams started in the Ploughing Match. The soil was less favorable than had been anticipated. The ploughing was well done considering some unfavorable circumstances attending it, but might have been better done had it been less hurried.

The procession moved at 11 o'clock to the South Meeting-house. The prayer by the Rev. Mr. Osgood, of Sterling, was solemn, pertinent, and impressive. The Address, by the Hon. Oliver Fiske, one of the board of trustees, was, in all respects worthy of the reputation of the author, and contained many useful lessons for the Farmer, the result of study and experience. It will soon be published under the direction of the trustees.

There was but one opinion expressed by the spectators, that a finer show had never been witnessed in this Commonwealth. A large portion of the young stock was of the Denton breed.

The following toasts were drank at the entertainment.

Our great Farm—the Commonwealth—The venerable Foreman employed in its oversight—and all able and faithful laborers who are engaged in its management on account and for the sole profit of its Legitimate Proprietors—the People.

The Economy of Massachusetts, a good Stock in the man—bad husbandry shows where it wants crossing.

The Interest of Manufactures, and the skill of the Manufacturer—may the one be justly appreciated, and the other wisely protected.

The Massachusetts Society for promoting Agriculture—It has not the credit of giving the first example of *ploughing Match*, to the other Societies of the Commonwealth, yet to them it has become, what with the *ough*, the heavy oxen at the beam are to the steers in the chain—the *strength and steadiness* which regulates the team, and carries out the furrow, to the end of the work.

The only path which can be made through the Ocean is the path of glory, which our enemies have found by beaten.

land Navigation—while it gains us new neighbors, shall not forget the claims of our own household.

Gen. H. A. S. Dearborn. May the patronage of Legislature cause the Connecticut to flow through Worcester, and make Boston her best neighbor.

The Middling Interest—As it respects animals may it be confined to Cities and Seaports. The Farmer counts the general interest by preferring his best stock.

our Next Cattle Show—May it find us with good in our fields, good flocks in our folds, good prizes in our hearts, good help-mates in our houses, to the Governor.

The Town and County of Worcester—whose improvements in Agriculture and the Useful Arts reflect honor on the compact centre of the real strength of the state. By Mr. Wells, Delegate from the Massachusetts Society.

The ambitious purposes of our Agriculturists—May they subdue the earth, not by war and desolation, but by multiplication of the means of subsistence and comforts of man.

By Mr. Durby, Delegate from the Massachusetts Society.

The Worcester Agricultural Society—Their interest in this exhibition this day evinces what can be effected by the emulation of improvement.

By Col. Eastis, of the U. S. Army.

the Worcester Exhibition of the noblest animal, which cannot be improved by crossing the breed with any foreign importation.

Commodore Bainbridge, Adjutant General, and Mr. Silsby, President of the Senate, gave complimentary toasts to the Society (the Exhibitions of the day: and the Sheriff of the County gave a complimentary toast to distinguished guests present.

In addition to the Governor and suite, there were present Com. Bainbridge, Hon. Mr. Silsby, President of the Senate of Massachusetts,

Mr. Crowninshield, of Salem, Gen. Dearborn, of Roxbury, Gen. Sumner, Messrs. Wells and Derby, Delegates from the State Society, and Col. Eastis, of the Army.

PREMIUMS AWARDED BY THE COMMITTEES.

On Neat Cattle—For the best Bull, Samuel of Charlton, \$15, next best, John W. Hubal, of Worcester, and Jacob W. Watson, of Princeton, 10. Best Bull Calf, John Brown, of Uxbridge, 6; next best, Alpheus Smith, Leicester, 5. Best Milch Cow, from a stock of five cows, Daniel Mixer, New-Braintree, 15; next best, three cows, Andrew Smith, Rutland, 10; next best, Henry Rogers, Worcester, 8. Best Calf, Job Rainger, New Braintree, 6; next best, Salem Towne, jun. Charlton, 5. Best Calf, Alpheus Smith, Leicester, 5; next best, Asa Waters, Millbury, 4. Best four years old Steers, Simeon Phelps, Sutton, 10. Best two years, Luther Whiting, do. 2; next best, Cummings, jr. do. 5. Best two years old Steers, Stephen Marsh, jr. do. 7; next best, Roylance, do. 4. Best Yearlings, Daniel Cheney, do. 5. Best fat Ox, Asa Pond, Petersham, 15; next best, Seth Wyman, Shrewsbury, 10.

On Ploughing Oxen—1st, Isaac Hathaway, Sutton, \$15. 2d, Freegrace Marble, do. 12. 3d, John Sherman, 2d, do. 10. 4th, Seth Wyman, Shrewsbury, 5.

On Sheep—Best Merino Ram, Bezaleel Taft, jr. Uxbridge, 10; next best, Joseph Thayer, do. 5. Best Merino Ewes, Aaron Tufts, Dudley, 10; next best, Salem Towne, jr. Charlton, 5. Best Merino Wethers, Bezaleel Taft, jr. Uxbridge, 4. Best lot mixed Merino Sheep, Rejoice Newton, Worcester, 5. Native do. Asa Rice, do. 1. Best Native Ram, Holton Maynard, Northboro', 5.

On Swine—Best Boar, Samuel Harrington, Worcester, 10. Best breeding Sow, Jonathan Knight, do. 6. Best weaned Pigs, Ward and Rice, do. 4.

Articles manufactured of Cotton, Wool, Flax and Silk—Best Broadcloth, Slater and Howard, Oxford, \$15. Best Cassimere, Wolcott Manufacturing Co. 10. Best Carpeting, Hannah Blair, Worcester, 15; next best, John Hunter, New Braintree, 10. Best Woolen Cloth, household manufacture, Samuel Dadman, Templeton, 8; 2d do. do. Lovett Peters, Westborough, 5; 3d do. do. Levi Sawyer, Bolton, 3. Best Flannel, Jonathan Wilder, Lancaster, 10; next best Jerome Gardner, Harvard, 5. Best Linen Sheet, Betsy Delano, New Braintree, 5. Best do. Shirting, Priscilla Putnam, Grafton, 3. Best Woolen Coverlid, Jonathan Moore, Holden, 4. Best Linen Table Diaper, Patty Leland, Grafton, 8; next best, Polly Leland, do. 5. Best half Stockings, Hannah Edson, 2. Sewing Silk, Lemuel Healy, Dudley, 5.

On all other Manufactured articles—Best Butter, Levi Goodale, West Boylston, \$7; next best, Ebenezer Dunbar, Leicester, 5.—Best Cheese, William Tufts, New Braintree 10; next best, Elisha Mathews, do. 5. Set of Machine Cards, Cheney Patch, Leicester, 20. Best dressed Calfskins, William Slocumb, Northboro', 10. Best Sole Leather, Phineas Davis, do. 5. Best Morocco, Joseph Griggs and Co. Millbury, 3. Best Ox Yoke, Simeon Hathaway, jun. Sutton, 6; next best, Andrew Buxton, do. 5.

An extra Premium of \$2 was recommended by the Company, and awarded by the Trustees to be paid to Ebenezer Mower, of Worcester, for Butter in cakes of superior neatness and flavor.

On ploughing—1st, Freegrace Marble, Plough 10, Ploughman 5, Driver 3. 2d William Eaton, jun. Plough 8, Ploughman 4, no driver. 3d, Nathan Heard, jun. Plough 6, Ploughman 3, Driver 1. 4th, Silas Dudley, Plough 4, Ploughman 2.

BERKSHIRE CATTLE SHOW.

This Exhibition was held on the 1st and 2d inst. The exhibition of Animals was very fine, including various breeds and cross-breeds, from different sections of the country. The quantity of Household Manufactures was small compared with that of former exhibitions, which was imputed to accident. The Ploughing Match, on the morning, was of much interest. The spectators were more numerous than had been before known. A numerous procession was escorted to the Meeting-house, (which was previously in part filled with an assembly of the fair and the fashionable) by the company of Berkshire Greys, under Capt. Clapp. The Prayer by the Rev. Dr. Shepard was peculiarly fervent and appropriate. The Address, by Theodore Sedgwick, Esq. of Stockbridge, was distinguished for good sense and good humor, and was well adapted to subserve the interest

of the practical agriculturist. This address will be published for the use of the Society. After the Address an elegant Ode, written by William C. Bryant, Esq. of Great Barrington (published on the last page of this day's paper), and set to music by Thomas Hastings, Esq. of Albany, was received with enthusiasm, heightened by the reflection that it was wholly American.

Elkanah Watson, Esq. of Albany, whose services in the formation of the Society were gratefully recollected, delivered some brief and pertinent remarks, accompanied by the present of a small treatise on Salt, &c. as a memento.

On the evening of the first day a Concert of Vocal Music was given under the direction of the Messrs. Hastings, of Albany, which was highly spoken of.

The Premiums were declared by the President, the Hon. H. W. Dwight, and were as follows:

Seth Wilcox, of Stockbridge, for the best two acres of Winter Wheat, \$9. The Committee observed that they had no doubt but this was the best crop of winter wheat raised within the Commonwealth this season. Oliver P. Dickinson, of Pittsfield, for the second best piece of Winter Wheat, \$6. Richard Cooman, of Pittsfield, for the best two acres of Spring Wheat, \$9. John Chamberlain, of Dalton, for the 2d best do. \$6. David C. Hull, of Stockbridge, for the best 3 acres of Winter Rye, \$9; Silas Smith, of Lanesborough, for the 2d best do. \$6; David Chapin, of Richmond, for the 3d best do. \$5; Erastus Rowley, of Richmond, for the 4th best do. \$1. Enos Smith, of Stockbridge, for a piece of Barley, \$1. Joseph Merrick, of Pittsfield, for the best 2 acres of Pease, \$5; James B. Ward, of Pittsfield, for the 2d best do. \$1.—Oliver P. Dickinson, of Pittsfield, for the best acre of Flax, \$3; Caleb Snow, of West Stockbridge, for the 2d best do. \$6; Erastus Rowley, of Richmond, for the 3d best do. \$1. Azariah Root, of Sheffield, for the best 3 acres of Oats, \$6; Timothy Wainwright, of Great Barrington, for the 2d best do. \$1. Jacob London, of Windsor, for the best 2 acres of Indian Corn, \$8; Chester Goodale, of Egremont, for the 2d best do. \$6; Samuel Kellogg, of Williamstown, for the 3d best do. \$5; William Whitney, of Stockbridge, for the 4th best do. \$1.

The Committee observed, "that in consequence of the severe drought in the early part of the season, the crops of Summer Wheat and Flax were much injured; yet, as the Society have thought proper to give liberal encouragement for raising these important crops, your committee did not think themselves at liberty to withhold the premiums on these crops, more especially on wheat. As it is a fact that by estimation more than 4,000 dollars is annually paid to the citizens of a neighboring state, by the inhabitants of one of our towns, for the article of wheat flour; a fact that calls loudly on the society for the encouragement of the cultivation of wheat." They likewise state, that "a crop of Winter Wheat, raised by Major Gen. Whiting, sowed after a corn crop would give at least 20 bushels; and on land that has been under cultivation for many years; which affords good evidence that wheat may be cultivated with profit on our old improved lands."

The Premium for the best cultivated farm was awarded to Samuel Kellogg, of Williamstown, \$20.

For Domestic Animals the awards were as follows, viz. To Isaac Reese, of West Stockbridge, for the best Bull, \$10; Abel Clark, of Richmond, 2d best do. \$8; Abishai Lewis, of West Stockbridge, 3d best do. \$6; Arvin Miller, of —, 4th best do. \$1. Levi Hinsdale, of Hinsdale, for the best yoke of Working Oxen, \$10; Levi Goodrich, of Pittsfield, 2d best, \$8; Aaron Roberts, of Dalton, 3d best do. \$6; Curtis Powell, of Pittsfield, 4th best do. \$1. Henry W. Dwight, of Stockbridge, for the two best Cows, \$10; Erastus Sacket, of Pittsfield, 2d best do. \$8; Charles Kellogg, of Dalton, 3d best do. \$6; John Chamberlain, of Dalton, 4th best do. \$1. Luther Sears, of Lenox, for the two best three years old Steers, broke to labor, \$10; Henry C. Brown, of Pittsfield, 2d best do. \$8; Hezekiah Porter, of Dalton, 3d best do. 5. Jonathan Y. Clark, of Pittsfield, for two best two years old Steers, 8; Erastus Sacket, of Pittsfield, 2d best do. 6; Joseph Woodbridge, of Stockbridge, 3d best do. 1. Henry W. Dwight, of Stockbridge, for the two best two years old Heifers, 8; Abishai Lewis, of West Stockbridge, 2d best do. 1. Thomas B. Strong, of Pittsfield, for the best Merino Ram, 8. Caleb Hyde, of Lenox, 2d best do. 5. Sam'l D. Colt, of Pittsfield, for the five best Merino Ewes, 6; Jonathan Allen, of do. 2d best do. 5; Elijah Robbins, of do. for the ten best common Ewes, 6. Levi Hinsdale, of Hinsdale, for the three best Swine, 6; Richard Cooman, of Pittsfield, 2d best do. 4. Samuel M. McKay, of Pittsfield, for the best Boar 6; Moses Tracy, of Richmond, 2d best do. 1. Obadiah Ward, of West Stockbridge, for the best Stud Horse 2.

A Bull of the short horned Durham breed, belonging to Stephen Williams, Esq. of Northborough, not exhibited, was noticed by the committee as a fine animal. Two premiums awarded to the President of the Society, amounting to *eighteen dollars*, were relinquished by him for the purpose of being awarded to the person who shall exhibit the best *Stock of Cattle* at the anniversary of 1821.

The committee regret that so little attention is paid to improve our breed of horses, believing the farmer cannot find a greater source of profit than would arise from raising those fine and useful animals. They likewise observed that the animals exhibited were, in general, superior in size and beauty, to those shown at any former period.

Six ox teams and one horse team were entered at the Ploughing Match. The premiums were as follows: To James Nichols, of Pittsfield, the 1st premium 10 dls.—Curtis Powel, 2d do. 8.—Levi Goodrich, 3d do. 6.—David Goodrich, 4th do. 1. There was no competition in horse teams. Abraham Bow alone entered, who did his work in a very skilful and expeditious manner, finishing his quarter of an acre in twenty-eight minutes, and receiving the first premium on horses of 6 dols.

Household Manufactures.—The committee speak highly of this branch of the exhibition, observing, in substance, that although not authorised to say that so large a quantity of goods have been exhibited as at some former exhibitions, they excelled in point of value and manufacture those on former occasions. The premiums were as follows: Woollen fulled Cloth, to Mrs. Wealthy Goodrich, of Pittsfield, 3 dols. 2d best to Mrs. Levi Hinsdale, of Hinsdale, 3;

3d do. to Mrs. Anna Cooman, Pittsfield, 4.—White Flannel, Miss Sophronia Tracy, Richmond, 6; 2d best, Mrs. Esther Plummer, do. 5. Linen Shirting, Miss Lucy Phelps, Pittsfield, 8; 2d best, Mrs. Laura Chapin, Richmond, 5. Linen Diaper, Mrs. Almira Nichols, do. 6; 2d best Mrs. Louisa Bliss, Stockbridge, 4. Carpeting, Mrs. Nancy Williams, do. 8. For the largest quantity of useful articles manufactured by one family, and by females since the last anniversary, &c. to Miss Catharine Pierson, Richmond, \$10; 2d largest quantity, Mrs. Sarah Perkins, Becket, 8 dols.

Reserved Premiums.—One piece of Imitation Caroline Plaid, Miss Lucy Phelps, Pittsfield, 6. One Grass Hat, in imitation of Leghorn, Mrs. Elizabeth Beard, Washington, 5. Three pairs Worsted Stockings, Miss Catharine Pierson, Richmond, 4. One piece Worsted Plaid, Mrs. Olive Tracy, Richmond, 3. One piece Linen Diaper, Mrs. Clarissa Dickinson, Pittsfield, 3. Cassimere Shawl, Mrs. Phebe Nichols, Richmond, 2. One Rose Blanket, Mrs. Eunice Rowley, Richmond 2.

The following gentlemen were elected Officers, for the ensuing year: Henry W. Dwight, President, Samuel M. McKay, 1st V. President, John Wells, 2d V. President, Ezekiel R. Colt, Cor. and Rec. Secretary, Samuel D. Colt, Treasurer; Thomas Melvill, Jr. Oliver P. Dickinson and Levi Goodrich, Committee on Agriculture; Phinehas Allen, Jonathan Allen, 2d. and Curtis T. Fenn, Committee on Manufactures; Thomas B. Strong, Richard Cooman and Jonathan Y. Clark, Committee on Animals.

NEW ENGLAND FARMER.

SATURDAY, OCTOBER 25, 1823.

BRIGHTON FAIR AND CATTLE SHOW.

Our last contained a brief outline of this exhibition; and the Reports of the Committees will better complete the picture than could any of our sketches. We shall merely add that the Festival was honored by the presence of his Excellency the Governor, His Honor the Lieut. Governor, and many other gentlemen of the highest standing and first character in the Commonwealth. The Public Dinner, on the first day, presented a feast of sentiment, as well as of the best fruits of the soil and the season. Previous to the entertainment, and after the guests were seated, Mr. LOWELL, President of the Society, addressed the company as follows:

"We are the only nation (we believe) on earth, which has been accustomed to introduce sentiments in our convivial meetings and solemn festivals. In the country from which we descended, the usage has been and still is to give toasts in honor of *individuals*, and often of *persons present*. The delicacy of our republican feeling has forbidden the introduction of this custom, at least, in these Northern States. Perhaps the origin of this delicacy may be traced to the peculiar character of our ancestors, who despised worldly distinctions, and sought for their reward only the testimony of an approving conscience, and of that Almighty Being, to whom they felt a solemn accountability. In the countries in which this species of *personal adulation* prevails, it is necessarily followed by *formal speeches*, in which the person *praised* endeavors to show that he *deserved* it, and in his turn, compliments in exaggerated terms, as well the person who offered the compliment, as those who *applauded* it. To minds not accustomed to these usages, there is something

revolting in them, and we feel a natural repugnance to this concerted bandying of mutual praise, as meaning as it is offensive to delicate minds.

"But we too, with our cold reserve as to *personal praise*, have our faults, and they are scarcely less injurious to the public welfare. We have been accustomed to make the sentiments, given at our social meetings, the vehicles of our party, personal and political feelings. One cannot hope at once to correct this habit so deeply rooted, but we may be permitted to say, that on occasions like the present (and wont to God they were more frequent) in which there is union (if but for a day) of men of all *political and religious* opinions, all sentiments which might give the slightest pain to any individual present ought to be suppressed. We are met to celebrate the triumphs of cultivated minds, in the agricultural and mechanical arts. These triumphs are confined to no sect—to no party—to no particular portion of our common country—they are the common estate, and pride of us all. Few sentiments only will be announced from the chair in which it is hoped we may all cordially unite."

Sentiments were then announced, after which others followed as volunteers by his Excellency Governor Eastis, His Honor Lieut. Gov. Lincoln, by members of the Executive Council, by the respectable Delegation from the Society at Worcester, by Judge Storrs, Judge Davis, the Hon. Mr. Webster, Professor Everett, Col. Thorndike, Mr. Winthrop, and many others. Although these were fraught with sound sense, good sense wit, perfect good humor, and a happy adaptability to the occasion, we shall omit all but the two following *volunteer* sentiments, for the reasons assigned by Mr. Lowell, in which we beg leave to express our perfect concurrence. Those which we here publish are retained because the former may be useful in combating a prejudice injurious to agricultural improvement, and the latter is a vehicle of morality and patriotism.

By Lieut. Gov. LINCOLN. "Gentlemen Farmers! A term heretofore, in common acceptance, of *equivoque* significance, but which the latest and most approved authorities—crops, improvement, and a Brighton Cattle Show—have defined to mean a class of disinterested, intelligent, successful, "though going;" practical agriculturists.

A basket of fine Peas, called "Bon Chretiens," [good christians] having been presented, from a tree planted by Gov. Endicott, in 1630, and now in a fruit-bearing state, on the farm of his lineal descendant, the Hon. Judge Davis paid the following neat compliments to the *Pilgrims*.

Governor ENDICOTT, and the "Bon Chretiens" thus accompanied him—*Good fruit, and long lived.*

A FINE COW.

In a note attached to the Report of the first Committee on Stock, exhibited at the late Brighton Cattle Show, of which Mr. Lowell was chairman, notice is taken of a Cow exhibited, owned by Charles Vaughan, Esq. of Hallowell, "from an imported breed, of great value, and without question one of the most perfect animals ever exhibited at Brighton." This cow, we learn, has since been slaughtered, and her weight was as follows:

Hile	79 lbs.
Tallow	93
175	2 hind quarters.
163	
190	2 fore quarters,
193	
903 whole weight.	

This fine animal, we are assured, has been at grass all the season, and had no provender till within a few

cks. This fact, considered in addition to her beautiful form must place her high in the estimation of judges of Near Cattle. It proves her to have in one of those animals which possess a great aptitude to fatten, a quality held in high estimation by discerning and calculating graziers.

Little Shows are pouring in upon us from various quarters in such abundance that we apprehend a scarcity of room in our columns. We fear we shall not be able within a pretty protracted period to give place to official accounts of all these exhibitions, or to publish many before they get to be old affairs. They will in course not be adapted to the curiosity of some readers, who are always all agog for novelty, and can scarcely endure a terrible earthquake, or a shocking derelict, which is more than a week old, although they are very fond of such articles when fresh from the press. We shall, however, proceed, as fast as possible at full accounts of each Husbandman's Holiday on record, that the agricultural Ladies and Gentlemen, who do us the honor, to take the New England Farmer, may compare the exhibitions of the present year with those of the last and future years. We must therefore beg Messrs. A. B. and C. to the end of the alphabet, to have patience; we will tell them all—unless we omit a part by inadvertence. Should such omission happen we will be much obliged to any of our friends who will forward the omitted statement, and it shall appear as soon as we can possibly find room for it.

FOREIGN.

The last advices from the seat of war in Europe are not so favorable as the first of September. It appears that at that time preparations were making not only for the bombardment of Cadiz, but for a descent on the Bay of Leon of a large and select body of troops, including the royal guards, to be supported by a powerful naval force. Events of much interest appear to be passing in that quarter of Spain. The French are soon to accomplish their objects, or return home, the Spaniards will let them and digest their disappointment as they can. A winter residence in Spain, for the inhabitants continue hostile, would be very uncomfortable, and somewhat dangerous for the French. It is true that the climate is not so "frigid" as that of Russia, but the country must by this time be very well exhausted of provisions, and cold lodgings, and stomachs and a bad cause will be apt to quell the ardor of the most fiery spirits that ever shouldered a musket, or charged with a bayonet.

The Greeks.—An article dated Zante, July 16th, states that the Greeks had gained an important victory over the Turks near Megara. "After two hours fighting the Turks were repulsed, and sought safety in flight, leaving behind them 2000 killed and 3000 prisoners; their wounded amounted to 3000." The whole of the Turkish artillery, ammunition, provisions, &c. fell into the hands of the conquerors.

Walter Scott, says an English paper, is fitting up a house at Abbotsford with gas light. The bells are rung by the pressure of air through a brass tube, in the wire now in use.

Derburgh, June 30.—A sad accident happened to a monarch, during his journey to Warsaw. His Majesty it is well known, is accustomed to travel in a manner. While passing a bridge near the city of Derburgh, the bridge broke through, and His Majesty's carriage fell into the river. The horses alarmed, endeavoring to release themselves from the carriage, turned it, and the Emperor seated in his open calash, received so severe a blow on the back of the head he lost much blood from the wound and fainted. Immediately the city of Derburgh was not far off, the Emperor was carried there, and visited by the best surgeons of the city, who pronounced that the wound would not be followed by serious consequences. The

Emperor ordered into his presence the two inspectors general of the roads, and having reprimanded them with their carelessness, banished them to Siberia.

DOMESTIC.

Tobacco.—Some accounts from the South inform that Tobacco, to the amount of one half the crop, has been destroyed by a frost on the 29th of September. But the Petersburg, (Virginia) Intelligencer, of the 10th inst. states that in that section of the country, and all south of it, there is reason to believe the damage sustained by the tobacco crops is comparatively but slight, and that the quantity brought to market will not be lessened materially.

Thanksgivings.—His Excellency Gov. Estis has appointed the 30th of November next, to be observed as a day of Public Thanksgiving and Prayer throughout this Commonwealth. The Governor of New York has appointed the 18th December to be observed as a day of Public Prayer and Thanksgiving. The 20th of November, in New Hampshire, and the 27th in Connecticut are appointed for the same purpose in those States.

Day of Thanksgiving and Prayer throughout the bounds of the Presbyterian Church in the U. States.—The General Assembly at Philadelphia, in May, set apart the first Thursday in November to be thus observed. As this denomination of Christians is confined principally to the middle and southern States, the state governments of which are not generally accustomed to appoint this religious anniversary, it seemed necessary for the Church to do it.

Stramonium.—A Long Island paper mentions that several children have been poisoned and barely escaped death by eating the seeds of *Stramonium*, (thorn apple or stink seed.) This plant is now in seed, and grows in almost every village.

Snow.—On Tuesday last, Sept. 30, the hills in this and the adjacent towns were covered with snow. We are informed that on the height of land in Washington, the snow was from three to four inches deep; presenting the appearance of winter.

Montpelier Watchman.

Sixty pounds of cloves have been gathered from a single tree in Hayti the past season, a specimen of which has been sent to Dr. Mitchell, of New York.—The person who sent it expressed a belief that the climate of Florida is capable of producing this spice.

There are in the state of Vermont 27 cotton and woollen factories—13 paper mills—256 fulling mills—250 carding machines—380 grain mills—389 physicians—224 lawyers—235 churches—1575 school houses, and about 150 distilleries.

The Grist, Chocolate, and Carding Mills, of Major Foster, at Danvers, were unfortunately consumed by fire, on Tuesday evening. Loss estimated at \$25,000.

Half Century Sermon.—The Rev. Nathan Perkins, D. D. of West Hartford, recently preached a sermon at the close of the 50th year of his ministry.

Andrew Jackson has been elected a Senator of the United States from the State of Tennessee, to succeed John Williams, whose term of service expired on the 3d day of March last.

ALDERNEY BULL FOR SALE.

THE very fine full blood ALDERNEY BULL, which was presented to the Massachusetts Society for promoting Agriculture by John Hubbard, Esq. This breed is considered in England, as superior for the richness of their milk, making considerable more butter from the same quantity of milk, than any other breed. He is now two years and three months old, is in fine health, and a gentle animal, and may be seen at the farm of John Prince, Esq. Jamaica Plain, Roxbury. For terms of sale, which will be very liberal, apply to JOHN LOWELL, Esq. or said Prince, in Roxbury.

Roxbury 30th Sept. 1823.

NEW ENGLAND MUSEUM,

76, COURT STREET, BOSTON.

CONTAINING much more numerous Collections and greater variety of entertainments than any other Establishment in America, continues steadily to increase, and is open for the reception of visitors

EVERY DAY AND EVENING.

It will be constantly in the best possible condition, and every exertion made to render the visits of its patrons agreeable.

This Establishment now contains FIVE former Museums united in ONE, together with very great and numerous additions (the whole receipts being faithfully laid out to increase it.)

JUST ADDED.

The celebrated Race Horse Eclipse, A beautiful Cosmorama View of London, A large and beautiful live Rattlesnake, The Arabian Bottle, made of the stomach of a Camel—holds about a barrel—used to carry water across the desert.

The Invalid's Chair—very ingenious—invented by Professor Peck.

A very large and elegant Sword Fish, upwards of 14 feet long, with a sword 4-2 feet long.

The Museum is well lighted, and a Band of Music performs every evening. Admittance 25 cents.

AN ODE,
FOR THE ANNUAL CELEBRATION OF THE BERKSHIRE
AGRICULTURAL SOCIETY, 1823.

BY WILLIAM C. BRYANT, ESQ.

Far back in the ages
The plough with wreaths was crown'd,
The hands of kings and sages
Entwined the chaplet round;
'Till men of spoil
Disdain'd the toil
By which the world was nourish'd,
And blood and pillage were the soil
In which their laurels flourish'd.
—Now the world her fault repairs,
The guilt that stains her story;
And weeps her crimes amid the cares
That form'd her earliest glory.
The proud throne shall crumble,
The diadem shall wane,
The tribes of earth shall humble
The pride of those who reign;
And war shall lay
His pomp away;
The fame that heroes cherish,
The glory earn'd in deadly fray,
Shall fade, decay and perish.
—Honor waits, o'er all the earth,
Through endless generations,
The art that calls the harvest forth,
And feeds the expectant nations.

From the N. H. Patriot.

JONATHAN'S ACCOUNT OF THE CATTLE SHOW.

Did y'e'ver to the Cattle Show go?
What kicking, and pushing and goring—
Cattle in pens—the pens in a row—
And tarm'd great hogs, there, a snoring.—
There's sheep too; ewes and weathers and lambs—
Some Bucks; (some are'n't in pens far's I know)
There's sheep of the Dons—some Uncle Sam's—
Some Natives—some "real Merino."
There's a tug too, or trial of strength,
With hawing and geeing and scolding,
Just to twitch a great stone a foot's length—
Haw! haw buck!—why don't ye!—gee golding!
Then for ploughing they give a reward,
And, *cute* as a squirrel cat burrows,
Off start the ploughs, cut through the green sward,
A turning the *slickest* of furrows.
And then, sir, in a room that they've got,
There's an "ocean of notions" display'd,
There's blankets, and stockings and—what not—
That the folks in their houses have made.
There's bonnets, both of straw and of grass,
And cloth too, of woollen and linen,
And there's yarn, and there's thread, smooth as
glass
That gals for themselves have been spinning.
There's hats, and there's shoes, and there's leather,
And there's—I can't tell half now, I hear—
Got a price—gee! ho! altogether!
And I'd go to the show twice a year. JOCK.

From the Boston Daily Advertiser.

WASHINGTON MONUMENT ASSOCIATION.

Several years having elapsed, since the subscriptions were paid in, several gentlemen have suggested, that it would be proper that the

contributors (scattered throughout the state) should be informed of the causes of delay in carrying the project into execution, of the present state of the property, and our future expectations, and have requested me to state them.

The Committee appointed to procure the Statue wrote to our distinguished artists, the late venerable Benjamin West, President of the Royal Academy of Painting, and to Washington Alston, Esq. both resident in London, and authorized them to select the sculptor in their opinion best qualified to execute the work in any part of Europe, and to contract with the person so selected, as the Committee were entirely unable to judge of the value of such services. They selected Mr. Chantry, of Pinlicko, near London, whose reputation is well known, and contracted with him for a marble statue, of colossal dimensions, but simply pedestrian, the fund not being adequate to the purchase of an equestrian statue.

Mr. Chantry frankly told Mr. Alston that he had works of art already engaged, which would occupy him for four years, which have expired. Col. Thomas H. Perkins having kindly offered his services on his late voyage to Europe, to ascertain the progress of the work and to urge its completion, I gave him a letter to Mr. Chantry. His report is, that a marble block of beautiful quality had been obtained, and that it is the expectation of Mr. Chantry to complete it and send it out within the next year.

The funds are under the care of the Treasurer, the Hon. P. C. Brooks, and I have the pleasure to state, that by his attention they amounted to \$14,739 on the first of October instant—so that there will probably be ample funds to complete the pedestal and other appendages. We may hope, in a short time, to see this too long delayed tribute to our greatest benefactor completed.

JOHN LOWELL,

Chairman of the Committee for procuring Washington's Statue.

Roxbury, Oct. 13, 1823.

Some days since, in the family of Mr. Moore, a gentleman residing near Shacklewell, at a family dinner, that gentleman, and four others, who sat down to the table, were all taken suddenly ill, with violent pains in the throat and stomach. A doctor was immediately sent for, when powerful emetics were administered, and after each of those affected had sustained dreadful illness, they were saved from the dreadful consequences, which there was reason to believe the poison would otherwise have produced. There was afterwards considerable difficulty in ascertaining in what way the poison had been taken. The wine was tried but it was found to be of an innocent quality. One of the sufferers stated that he felt a "coppery" taste in his mouth, and this led to an examination of the French beans, which had been eaten at dinner, and which were found to be highly impregnated with copper. It ultimately turned out that the cook, who had not been long in the situation, had put a dozen of half-pence in the pan in which she boiled those vegetables, and by that means gave them that fine green which they possessed. This she had always been accustomed to do, and there is great reason to believe that this highly reprehensible and dangerous practice is pursued very

generally by ignorant cooks, to give their vegetables the green color, which so many persons foolishly consider as a recommendation, and a test of their excellence. We understand that all the sufferers are now perfectly recovered.—*London Paper.*

In the centre of the Museum in Dublin, suspended the skeleton of a grampus, fifteen twenty feet in length. The preparations this museum are numerous and valuable: among those are two rare and celebrated specimens. One of these is the skeleton of one Clark, native of Cork, who it is said was a young man of surprising strength and agility; but having once laid all night in a field after indulging in great dissipation, the left part of his body began to ossify, and the process continued by slow degrees, until every part grew into a bony substance, excepting his skin, eyes and entrails. His joints became stiffened, so that he could neither bend his body, lie down nor rise without assistance: when placed upright, like a statue he could stand; but move no more than if dead. His teeth were joined, and formed into one central bone, so that it became necessary to break hole through them to convey liquid substance to preserve a miserable life. His tongue to its use, and his sight left him sometime before he expired. This preparation shows the progress of this singular instance of a disease, parallel to which is not perhaps to be found any other collection.—*Griscom's Year in Europe.*

Marble Ponds in Persia.—This natural curiosity consists of certain ponds, or plashe whose indolent waters, by a slow and regular process, stagnate, concrete, and petrify, producing that beautiful transparent stone, common called Tabriz marble, much used in the burial places of Persia, and in their best edifices. These ponds are contained within the circumference of half a mile, and their position is distinguished by heaps of stone which have accumulated as the excavations have increased. The petrificative process may be traced from its commencement to its termination; in one part the water is clear; in a second, it appears thick and stagnant; in a third, quite black; and in its last stage, it is white like a hoar frost. When the operation is complete, a stone thrown on its surface, makes no impression, and a man may walk over it without wetting his shoes. Such is the constant tendency of this water to become stone, that when it exudes from the ground in bubbles, the petrification assumes a globular shape, as if the bubbles of a spring, by a stroke of magic, had been arrested in their play, and metamorphosed into stone.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscribing will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the Publisher) until arrearages are paid.

Agents who procure seven subscribers, and be considered responsible for the payment, will be entitled to a copy gratis, and in the same proportion for a larger number.

Subscribers to the N. E. Farmer are requested not to pay any money to Travelling Agents, on account of the paper, as Agents of this description are not authorized to receive money on our account. Sept. 27.

BOSTON, SATURDAY, NOVEMBER 1, 1823.

No. 11.

RIGHTON CATTLE SHOW.

REPORT No. V.

BRIGHTON, OCT. 16, 1823.

The Committee appointed to award premiums on the Ploughing by single teams, or by yoke of oxen, have attended to the duty assigned them, and report as follows, viz:—That persons entered as competitors, and drew the eleven lots laid out by the Committee arrangements as follows:

- No. 9.—Joseph Dudley, of Sutton, Himself, Ploughman, ———, Driver.
performed in 26 minutes—12 furrows turned.
- No. 10.—Lincoln Fearing, of Boston, E. Cushing, Ploughman, Giles Woodman, Driver.
performed in 29 1-2 minutes—10 furrows turned.
- No. 11.—Silas Dudley, of Sutton, Himself, Ploughman, Isaac Hathaway, Driver.
performed in 31 minutes—13 furrows turned.
- No. 12.—Leonard Stone, of Watertown, Solomon Sargent, Ploughman, Jonas Smith, Driver.
performed in 28 1-2 minutes—13 furrows turned.
- No. 13.—Isaac Cook, of Brookline, Isaac Cook, jr. Ploughman, Isaac Cook, jr. Driver.
performed in 35 minutes—13 furrows turned.
- No. 14.—Stephen Marsh, of Sutton, Simon Phelps, Ploughman, Stephen Marsh, Driver.
performed in 27 minutes—12 furrows turned.
- No. 15.—Aaron Davis Williams, of Roxbury, Lewis Barker, Ploughman, Lewis Bliss, Driver.
performed in 31 2-2 minutes—14 furrows turned.
- No. 16.—Joseph Miles, of Concord, Silas Lee, Ploughman, Joseph Miles, Driver.
performed in 25 minutes—11 furrows turned.

The committee feel it a duty to report, that the work was well performed, and did great credit to the performers; but having only three yokes to bestow, after due deliberation, they examined the work carefully award as follows:—

- Isaac Cook, of Brookline, the first premium, \$15
- Isaac Cook, jr. as Ploughman, 8
- Isaac Cook, jr. having no driver, 4
- \$27
- Aaron Davis Williams, of Roxbury, the second premium, \$10
- Lewis Barker, Ploughman, 5
- Lewis Bliss, Driver, 3
- \$18
- Joseph Dudley, of Sutton, the third premium, \$6
- Silas Dudley, as Ploughman, 3
- Isaac Hathaway, Driver, 2
- \$11

The committee found some difficulty in deciding the premiums, and regretted that they did not at least one more to bestow, but have ventured to award in the best manner the use of the subject would permit. All which is respectfully submitted. (Signed)

GORHAM PARSONS, Chairman.
ICHABOD NICHOLS,
FRANCIS WINSHIP.

REPORT No. VI.

BRIGHTON, OCT. 16, 1823.

The Committee on the Ploughing Match of two pair of oxen to plough one quarter of an acre, consisting of John Prince as chairman, and Josiah Titcomb and Paul Upton, beg leave to report their opinion and award of premiums:

That four ploughs only were entered to contend for the three premiums; that the ploughmen drew for lots as follows:

No. 1.—John Sherman, of Sutton, with plough and wheel on the end of the beam, made by J. Hall, of Sutton—said Sherman himself ploughman, and Austin Sherman, driver.

No. 2.—Stedman Williams, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel on the beam—said Williams, ploughman, and Samuel Prime, driver.

No. 3.—Joseph Curtis, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel and cutter—Amos Wymann ploughman, and Aaron Stone, driver.

No. 4.—Aaron Davis Williams, of Roxbury, plough made by Jesse Warren, of Dedham, with wheel and cutter—Thomas Howe, ploughman, and David Howe, driver.

The rules and regulations were explicitly stated to the ploughmen, particularly that *goodness of work, the state of the cattle when finished, and time*, would be taken as criterions in deciding the premiums—and that the Committee did not wish the cattle to be hurried, as good work could not be well done, when over driven. They have great satisfaction in stating that the work was all exceedingly well performed, and the cattle came out in good order and could all of them, with ease, have proceeded to double the work if required. The only difficulty the committee experience is in deciding, and they trust, from the pains they took, that the unsuccessful competitor will not feel dissatisfied, although he was the only one that could not obtain a premium; they much wish they had a fourth to give him.

No. 1 finished their task in 48 minutes 20 sec. with 28 furrows in 24 feet width, making 10 1-3 inches per furrow—the cattle 3 and 4 years old.

No. 2 finished in 44 minutes 20 sec. with 26 furrows in 24 feet, making 11 inches per furrow—cattle 3 and 8 years old.

No. 3 finished in 49 minutes 30 sec. with 26 furrows in 24 feet, making 11 inches per furrow—cattle 7 and 8 years old.

No. 4 finished in 49 minutes, with 28 furrows in 24 feet, making 10 1-3 inches per furrow—cattle 6 years old.

The chairman having stated his wish to the Committee that they should agree on the premiums, if not, he would be called to the unpleasant task of deciding—which he is happy to inform the Trustees he was not required to do, the committee agreeing in opinion to award as follows:—The first premium to

- Stedman Williams—plough \$15
- Himself, ploughman, 8
- Samuel Prime, driver, 4
- 27

- 3d prem.—John Sherman—plough \$10
- Himself, ploughman, 5
- Austin Sherman, driver, 3
- \$13

- 3d prem.—Aaron D. Williams—plough 6
- Thomas Howe, ploughman, 3
- David Howe, driver, 2
- \$11

They feel themselves in duty bound to state, that the goodness and well training of the 3 and 4 years old cattle of Mr. Sherman would have given him a fair claim for the first premium, had he not made two or three baulks in his work. They would also state, that the work of Mr. Curtis's plough was very fine, but rather shallower than their rule, or of any other plough.

The Committee feel satisfied that all engaged exerted themselves to their utmost, in doing good work, and they only regret, that there had not been more competitors, that they should not have had the unpleasant feelings of leaving a solitary, faithful and deserving one.

JOHN PRINCE,
JOSIAH TITCOMP,
PAUL UPTON.

No. VII.—ON WORKING CATTLE.

The Committee of the Massachusetts Society for the Promotion of Agriculture, consisting of Messrs. John Welles, Silas Gates, Elijah Perry, and Nathaniel Tucker, having been appointed to consider the several claims for premiums to the Working Oxen, duly entered at the Cattle Show at Brighton, on the 16th of October, 1823, have attended to that duty, and Report: That they are enabled to congratulate the Society upon the good effects of the encouragement given by them to the rearing, training and improving of the Ox Team, of the importance and utility of which they have a strong sense.

Ten yoke of Cattle were entered to contend for the premiums, and they did honor to the farmers who owned them.

The committee proceeded to compare them in reference to their *age, strength, size, form, and beauty, equality of match, and other general circumstances*; and, after a minute examination, and such test of their power and training as could well be had, they award as follows:—

- To John Sherman, of Sutton, his twin cattle, 4 years old, 1st premium, \$30
- To John Scammel, of Bellingham, his cattle, four years old, 2d premium, 25
- To Isaac Hathaway, of Sutton, his cattle, four years old, 3d premium, 20
- To Stephen Marsh, of Sutton, his cattle, 5 years old, 4th premium, 15
- To Isaac Stone, of Watertown, his cattle, 5 years old, half of 5th premium, 7 50
- To Simon Phelps, of Sutton, his cattle, 4 years old, half of 5th premium, 7 50

The committee have a full conviction of the motives of the "Society for the Promotion of Agriculture," in extending to the simple operations of labor, by the best selected and judiciously trained cattle, in five several gradations, the most liberal encouragement and reward. The admirable fitness of this power, in cultiva-

tion, for our soil,—its cheapness of support,—the ease with which it is reared,—its certain and regular increase in worth, and its intrinsic value in case of accident, should be sufficient inducement to its universal use, and preclude the necessity of persuasion.

But the fact is not to be disguised! The Horse is too often substituted for the Ox, and when maintained beyond necessity, becomes a source of consuming expenditure. The great increase of this animal has, in several parts of Europe, been thought the mean of public inconvenience and distress.

Is it not then a dictate of sound consideration with the Farmer, not to multiply the Horse (the greatest consumer of all animals of the means of support to man) beyond his convenience and necessity; whose value depends on so many casualties, and ceases with his breath, in preference to the Ox, whose utility has been tested by long tried, and well founded experience? who when he ceases to improve is made to add to our means of support, and to enlarge the interests of the community; every effort to advance which, should be zealously supported by the Agriculturists of Massachusetts.—All which is submitted by

JOHN WELLES,
SILAS GATES,
ELIJAH FERRY,
NATHL. TUCKER.

REPORT NO. VIII.

BRIGHTON, OCT. 16, 1823.

The Committee on Agricultural Experiments, to whom was also committed the inspection of sundry articles of manufacture, for which premiums were offered, report:

That six parcels of Cheese, of more than a year old; and fifteen parcels of new Cheese, were offered for the Society's premiums; much of it, in the opinion of your committee, superior to any hitherto exhibited; marking, most evidently, improvement in the quality of this article. All the Cheese exhibited was from the town of New Braintree, in the County of Worcester; excepting one parcel of four Cheeses, entered by Mr. Jacob Osgood, of Andover, in the County of Essex, which was well made and of good quality. Of the old Cheese, that from the dairy of Mr. Job Rainger, was considered to be the richest and best made, and is entitled to the premium of ten dollars—that from the dairy of Mr. Elisha Mathews, the next best, and is entitled to the premium of five dollars. Of the new Cheese, that from the dairy of Mr. Joseph Green, was adjudged to be the best, and is entitled to the premium of ten dollars—that from the dairy of Mr. Alpheus Gilbert, the next best, and is entitled to the premium of five dollars.

Ten specimens of Butter were entered for premium, most of which is of an excellent quality—that from the dairy of Mr. Jonathan Upham, of Newton, was considered to be the best, and is entitled to the premium of fifteen dollars—that from the dairy of Stephen Hastings, of Sterling, the next best, and is entitled to the premium of ten dollars—that from the dairy of Mr. Jephthah Parker, of Chelmsford, the next best, and is entitled to the premium of seven dollars—and that from the dairy of the Rev. Lemuel Capen, of South Boston, being in lumps, and made in June last, the next best, and is entitled to the premium of five dollars.

Mr. Gideon Delano, of New Braintree, offered specimens of Butter, and Cheese, which are of a good quality, made between the 15th day of May and the first day of October, from ten cows, fed exclusively upon grass—the entire quantity of Cheese being 2744 lbs. and of Butter 171 lbs. Your Committee recommend that the premium of twenty dollars be granted to said Delano.

Mr. Samuel Hobbs, of Weston, is entitled to the premium of ten dollars, for the best dressed Calf Skins—and Mr. H. H. Hild, of Framingham, to the premium of five dollars, for the next best.

Five sides of Sole Leather were entered by Messrs. Benjamin Myrick & Co. of Roxbury, but your Committee did not consider them sufficiently well manufactured to be entitled to the Society's premium—the leather not being of an uncommon good quality.

Four specimens of Currant Wine were entered for the Society's premium; that offered by John Prince, Esq. was considered to be the best, and is entitled to the premium of ten dollars—John Kenrick, Esq. of Newton, is entitled to the premium of five dollars, for the next best.

A specimen of Wine made from the Elderberry, by Thomas Spencer, of Beverly, was exhibited; it appeared to be a pleasant, and is said to be a wholesome liquor, but one on which no premium was offered by the Society; your Committee recommend that a gratuity of three dollars be paid by the Treasurer to said Spencer.

Some canisters of Mustard, manufactured by Messrs. Bickford & Kellogg, of Boston, were entered for exhibition, and were found on trial to be equal, if not superior to any imported—no premium was offered by the Society for this article.

By order of the Committee.

THOMAS L. WINTHROP, *Chairman.*

The further claims for premiums on Agricultural Experiments, will not be decided upon until the Trustees' meeting in December next, affording time for the competitors to exhibit the evidence required; soon thereafter the Committee will make and publish an additional Report.

HARTFORD CATTLE SHOW.

On Wednesday the 8th of October, the Hartford County Agricultural Society held their 6th anniversary Cattle Show and Fair, in the city of Hartford.

An official Report of this Exhibition was prepared by Dr. Comstock, the Corresponding Secretary of the Society, from which we have made the following abstract and selections:

The exhibition of the present year, compared with those of former years, in some respects by far exceeded any former Show. The animals were more than double in number, and superior in quality; particularly the *Working Oxen*, *Three years old Steers*, and *Bulls*. The *Sheep* were few in number, compared with what might have been exhibited, did the farmers pay proper attention to this kind of stock. The *Swine* were many of them of the first quality, but the number less than was expected. Dr. Comstock remarks that "this being an animal which almost every house-keeper in the country fats for his own use, it becomes a mat-

ter of great importance that the best breed should be generally introduced. Farmers, others, therefore, who possess the best breed would undoubtedly find it to their advantage exhibit them. The *Cows* were commended for number and quality, and the *long team* of yokes, mostly of red oxen, excited great attention.

Domestic Manufactures.—The specimens *blue Broadcloths* were good; some of them respect to fineness of fabric, dressing and color were highly creditable to the skill of the manufacturer. The *Flannels* were nearly double in quantity to what had been offered before, and some pieces of superior quality. "We noted in particular, for its fine quality, a piece filled with cotton, and offered by Mr. Ira Wyster, but on which no premium could be given because it was not entirely of wool."

Of *Linen Diapers* there was a fine display. One piece in particular was said to exceed, consisted of 20 yards of real Damask Table Linen; the figures, those of birds. It was offered by Miss Mary L. Porter, of Farmington.

Of *Flannel Blankets* there was a delicious which it is hoped the next Fair will remedy.

Of *Coverlets* and *Counterpanes* there was a handsome display. "On these two articles Society have heretofore offered no premium it is however hoped they will be included next year."

Carpets.—"A very beautiful piece offered Mr. Lemuel Howlet, of Hartford, could not receive the premium because it was partly made of tow or cotton. We hope the next year the custom will be changed, for there is certainly more merit in making an equally good carpet of tow and wool than of wool alone."

Sockings.—These were woollen, worsted, linen, cotton and silk. "Some of the specimens were of the finest quality. The linen and cotton pairs which took the premiums were beautiful specimens of the art of knitting."

"*Bonnets.*—In this article, it is believed Shows have generally exceeded in beauty and fineness, any other in this country. This year we are sorry to see so little competition on article so costly, and so generally in use. The truth is our ladies ought to make their own Leghorns. Experiment has shown that it is possible within the country, both materials and ingenuity to fabricate as beautiful hats as can be made any where. The saving of cash to the county would be many thousand dollars yearly, if this was done. Among the bonnets we noticed one made of straw, which was pronounced by competent judges superior in beauty and fineness to any specimen ever seen in our shows."

Hearth Rugs, Butter and Cheese are taken notice of, but offer nothing remarkable.

Among the miscellaneous specimens of metal were a collection of *Coins* from the cabinet of the Rev. Mr. Robbins, of East Windsor, consisting of 342 pieces, viz. 210 of copper, 10 of silver, and 26 alloy. The dates are chiefly within 200 years, and many of them rare and valuable.

"As a specimen of Domestic Manufacture, nothing ever exhibited at our shows can be compared with a *Clock* manufactured and offered by Miss Sarah H. Hubbard, of Wintonbury. The colors, in imitation of the Scotch Plaid, were on the whole more beautifully and tastefully

arranged, than in any specimen of that we remember to have seen. The fabric exceedingly fine and soft cassimere. The lined with the skin of moles, and the presenting a very superb article of apparel. Miss H. also presented a *long Shawl* of mere, with a beautiful border, worked by H. The Society awarded Miss H. \$5, an premium for the cloak."

Bull of the full blood Devonshire Stock, bred by Mr. Hurlbut, of Winchester, was said to be the most perfect animal of the Ox kind seen at our Shows, or perhaps in the coun-

try. *Infant's Cap*, of fine Lace, done in a fair manner by Miss Alice Cogswell, of Hartford, who is deaf and dumb, was one of the most curious and interesting specimens of art we have ever seen. No description gives the reader an idea of this article." *Well Combs*, by Mr. Platt and Mr. Ruger. *Water Proof Fur Hats* by Mr. Hoadley Messrs. Wildman & Hamilton. *Bed Posts* of lignous wood—Two elegant *Chaises*, made at the Factory of Mr. Wing, and the one at that of Mr. Gaines, all of Hartford, are spoken of in terms of approbation.

The *Sweet Potatoes*, raised by Mr. Martiny, of Hartford, attracted particular notice. A piece of *Linon Diaper*, from Mrs. Bates of Norfolk, was considered not inferior to the article of the kind ever seen at our Shows.

The *Viewing Committee* reported—That in their official capacity, they have been called upon to view five farms.

The farm of Mr. Jefferey O. Phelps, of Simsbury, consists of about 120 acres. The attention of the committee was more immediately directed to fifty-one acres, lying in oblong, between the main road and the river.

This tract of land has been in the possession of Mr. Phelps, but a few years, and when it came into his hands, the whole of it with the exception of a few acres, was altogether unimproved. Two separate patches, of a light soil, were worn out, by a yearly repetition of the same crops—a large frog pond had been allowed to extend itself, in the form of a marsh, and the remainder was overgrown with white-bush, hard-hack, and laurel. In the period of three years, most of this has been reclaimed, but rendered highly unproductive. The low lands have been effectually drained; the decomposed vegetable matter, from the drains, has been applied, with success, to the parts, which were exhausted by tillage;—the bushes have been eradicated, the frog pond and marsh have been converted into an unusually beautiful and productive meadow lot.

Moses Goodman's farm in West-Hartford, contains about one hundred acres, and presents several valuable improvements. That which is the most productive part of this farm is a tract of low land, of about twenty acres. This is so dreached, by a small stream, which flows so it, and spread itself over it; and so fertilized by springs, issuing from the base of the land, by which the flat is surrounded, as to be wholly unfit for any agricultural purpose. It has been drained in a cheap, but effectual manner;—the growth of bushes removed;—and the mirey parts rendered firm, by frequent dressings of sand and gravel. The sit-

uation of this tract is such, that it is subject to occasional inundations. To rescue a part from the effect of freshets, and to render it subservient to the various purposes of tillage, an embankment is thrown up, in a very workmanlike manner, answering, at once, the purpose of a fence, a ditch, and a dike.—Mr. Goodman's attention, has by no means been confined to this part of his farm, but the whole exhibits traces of care, labor, and ingenuity. The orchards are thrifty, and of choice fruit, and the fences well built; this farm, deserves notice; and the dairy, though not large, is a source of very handsome profit.

The committee also viewed, in West-Hartford, the farm of Mr. Russell St. John, containing about fifty acres. Although naturally feasible, some parts of this farm had been allowed to run waste; and though originally not destitute of fertility, the rest had become nearly so, by an injudicious and improvident course of cultivation. The attention of Mr. St. John seems to have been directed to every part of his farm, and the crops taken from it, prove that labor has not been spent in vain. The fencing on this farm is defective, being made of weak and perishable materials; but a course of farming is pursued, which has eventuated in an increased amount of produce, and we cannot but admire that a young man, with limited resources, and almost entirely by his own hands, has caused this farm, in so short a time, to assume such a neat and tidy appearance.

The committee were gratified, in being again called upon to witness the agricultural operations of Mr. Oakes, on his farm in West Hartford.—This farm has now become well known, by the Reports of the Reviewing Committee, the two last years, and by having been visited by many intelligent and scientific farmers, from different parts of the county. The zeal and intelligence which Mr. Oakes has heretofore displayed, have not in the least abated;—but on the contrary, his success seems to have increased his ardor, and his experience to have added to his skill. When it is considered what this farm was, but three years since, it will be admitted that too much credit cannot be given to the enlightened proprietor, who originated, and who with the application of moderate means, has brought to perfection improvements so extensive and diversified.

The farm of Mr. Fontienne Raphael, in the south part of Hartford, was viewed by the Committee last year, and the improvements made upon it, were noticed in their Report. It will be sufficient to remark that the *neatness, order and regularity*, observable then, are still the prominent traits in the farming operations of Mr. Raphael. His quickness in perceiving what is desirable, combined with a readiness to apply the most direct and efficient means to accomplish the end proposed, is a faculty which few of our farmers possess, and which can be acquired only by long experience, severe thought, and the habit of reflection.

We would add, as a fact of primary importance, that in all their operations the owners of the several farms which we have visited, appear to have adhered to principles of strict economy. The beneficial changes which we have noticed, have been made with comparatively small expense; and the several improvements have been effected, by means, within the reach of almost every farmer in the country.

The examples which have fallen under the observation of the Viewing Committee in this, and the preceding years, evince, that nothing but *well directed industry* is wanting, to give every free-holder competent wealth, and to cause every part of our country to blossom as the rose.

The Committee award to Mr. Frederick Oakes, the premium of 30 Dollars for the best cultivated Farm.

To Mr. Fontienne Raphael, the premium of 20 Dollars for the second best cultivated Farm.

To Mr. Jeffery O. Phelps, the premium of 20 Dollars for the third best cultivated Farm.

By order of the Viewing Committee,
SAMUEL S. STEBBINS, Chairman.

Extracts from the Speech of Gov. Van Ness to the Legislature of Vermont.

Agriculture is our leading employment and principal support, and deserves every attention and encouragement that can in any manner tend to the advancement of its permanent prosperity. It is the most ancient and most useful of all employments. And the general diffusion of this sentiment, and the cultivation of an habitual regard for it, will be sure to conduce to the welfare of the state.

Considerable improvements have been made, within a few years, as it respects the tillage of the soil, and the breed and treatment of domestic animals. These have proceeded, in a great measure, from the spirit of emulation and enquiry excited by the establishment of agricultural societies. To the same source may be traced an improvement in that commendable industry in families, which is directed to the manufacture of articles of clothing, from materials produced on their own farms. These societies do not generally continue to be supported with the same zeal that organized them, though the same good effects thus far produced by them, will no doubt be lasting. If it should be considered of much consequence to have them kept up, and their exertions continue to advantage, it would be expedient to afford them some aid, by which they may be better able to distribute premiums, that being one of the most effectual means of their usefulness.

* * * * *

On the success of our manufacturing industry depends essentially the prosperity of agriculture; as by the establishment of manufactories is created a market for the articles necessary for manufacturing and for subsistence. And there appears good reason to justify the opinion, that by cherishing the resources of our own country, and protecting the industry of our own citizens, we might soon be able without going abroad, to obtain a ready supply of our wants, and to find a profitable and steady market for our produce. But if, on the other hand, we should persevere in the course we have been pursuing, if no barrier is erected to the vast importations of foreign merchandize, by which the exertions of our manufacturers have been systematically paralyzed, and the debts as well as the habits of extravagance of our citizens constantly increased, it would seem that a period cannot be far distant, which will overwhelm us with difficulties of a most serious and alarming nature.

Extracts from a "Journal of a Horticultural Tour through some parts of Flanders, Holland, and the North of France, by a Deputation of the Caledonian Horticultural Society."

STEAM IN HOT-HOUSES.

"For increasing and keeping steady the temperature in several of his hot-houses, Mr. Andrews has of late employed steam, in aid of the ordinary flues conveying smoke and heated air. The steam is carried through the house by means of metal pipes, which are laid along the top of the brick flues. The pipes are of copper, on account of its expanding less than lead. They are of a square form, and are set on edge, so that any condensed vapor trickling to the bottom may occupy but little room, or present only a small surface. As in the common steam engine, the boiler is made to regulate itself by a simple contrivance: it is furnished with a float, which descending in proportion as the water is dissipated in steam, in due time raises a valve and admits a new supply of water.—The superfluous condensed vapor also returns to the boiler, there being no other provision for disposing of it. It is scarcely necessary to add, that by merely opening a valve, the house can at pleasure be steamed, i. e. filled with steam, than which nothing can be more conducive to the health and vigor of plants confined in a hot-house. We were assured that seven bushels of coal go as far in keeping up the steam-heat, as ten bushels do in maintaining an equal temperature the other way. When the aid of steam is resorted to, the temperature is found to be more easily regulated, continuing equable for a considerable length of time. Mr. Andrews Junior, mentioned, that the furnace being duly charged, and the boiler prepared, he could with confidence leave the hot-house for eight or even ten hours together, being satisfied that the temperature would continue to be maintained for that length of time."

MARKET FOR BUTCHER'S MEAT.

"The market for butcher's meat in Ghent is kept extremely neat and clean; no offensive streams of blood are to be seen, every thing of that sort being confined to the shambles. Each dealer in meat keeps a carpenter's plane, with which he daily shaves the surface of the table of his stall; so that a stranger would be apt to think that all the tables were new."

MANNER OF FORCING RASPBERRIES.

"Raspberries are forced at Haarlem. The bushes are planted on the North and South sides of a pit filled with tanner's bark, leaves or stable-litter. The shoots of last year were at this time laid down to a horizontal trellis [structure of wood or iron] where they had yielded fruit in the vernal months. All means of artificial heat were now (the 29th August) of course removed. The shoots of this year were allowed to spring upright; and these will in their turn be laid down to the trellis at the approach of winter, when the others will be cut away. The gardener told us that raspberry plants thus treated yield large crops; and doubtless they are better adapted to this mode of forcing than vines."

ON RAISING NEW VARIETIES OF FRUIT.

"The experience of Mr. Van Mons (a famous Dutch horticulturist) confirms what has

been observed by British horticulturists,—that the fruit produced by a seedling tree in the first year of bearing, affords by no means a fair criterion of its future merit. If a pear or an apple possess promising qualities, a white and heavy pulp, with juice of rather pungent acidity, it may be expected in the second, third and subsequent years greatly to improve, in size and flavor; particularly if the buds, leaves, bark and wood possess the characteristics of approved bearing trees. Mr. Van Mons added a remark which we do not recollect to have met with in horticultural writings—That by sowing the seeds of new varieties of fruits, we may expect with much greater probability to obtain other new kinds of good quality, than by employing the seeds even of the best old established sorts. He likewise gave it as his opinion that if the kernels of old varieties were to be sown it would be better to employ those of other countries similar in climate."

NOTICES OF ENGLISH GARDENS AND HOT-HOUSES.

"Mr. Grange, of Hoxton, in the neighborhood of London, has fifty-seven acres under the spade. It is about seventeen years since he took possession of his grounds, and all the erections on them, connected with his establishment, which are very considerable, have been done at his own expense. It appears from a sketch which I took, that the hot-houses he had erected might be about 500 feet in extent; a great part of which were double roofed houses, projecting at right angles from a range of about 200 feet. At the back of these, sheds extend the whole length, suitably fitted up for the accommodation of his servants and other purposes. It forms the largest establishment of the kind that ever fell under our notice. He has introduced steam into two of his houses, in which he forces early strawberries, grapes and French beans to a great extent. In these houses stages are erected pretty near the glass for supporting the pots. He had about 15,000 pots of the Roseberry-strawberry plant ready for forcing, and said he had not been without ripe strawberries for 13 months past. When Mr. Grange shall have finished the extensive suit of hot-houses he is now erecting, and which is to be heated by steam, he intends to force peaches, grapes, cherries, figs, pine apples, jargonelle-pears and apricots. He has also a large ice-house, chiefly above ground, and entirely built of wood. It is divided into three parts, and its roof has much the figure of a large Dutch barn, approaching to the ground, and thatched five or six feet thick. When the ice in the first division is consumed, he opens a door into the second, and works through it into the third division. He keeps this for the supply of his elegant fruit-shop in Westminster with ice."

At Bruges, in Flanders, on the 12th of August, the Committee observe: "In the course of our evening walk, we were attracted by a novel appearance in husbandry, the labors of the seed time and harvest seeming here to be united and contemporaneous. We entered a fine field of luxuriant rye, part of which remained uncut, but a large proportion had been cut down this morning, (August 12.) The crop had been carried aside; well rotted dung had been pretty liberally laid on the stubble; the Flemish plough was now at work; and to com-

plete this picture of industry and expedition, a man was actually engaged in sowing turning the same portions of the ploughed fields, which the rye crop had been reaped in morning."*

"We must not omit to take notice of a large sort of hoe used for cleaning the gravel walks in the Duke of Ardenberg's garden is worked by two men, and is furnished with wheels, which greatly facilitate its movement. One man pulls forward, while the other guides the hoe, according to the nature and dance of the weeds to be extirpated. The patch thus afforded is great; two men I able effectually, and without interfering with the other garden operations, to do the which formerly occupied six men, to the lect of the ordinary business of the garden the time. It is best suited to the clean light sandy walks, but a similar implement might, in many places, where there are e sive gravel walks, be advantageously employed." A similar hoe is likewise in use in gardens near Paris.

"The last number of the Massachusetts Agrier Repository contains the following remark on this size: "This example ought not to be lost on us, as it is much more powerful, and our vegetation rapid than in Flanders. We know that some of us raise second crops with us; but may we not the system much farther? We certainly can do limiting the extent of our cultivated grounds, and allowing greater labor on the quantity we do cultivate, a remarkable example of raising turnips as and crop, we would refer to the statement of Daniel Esq. published in the first vol. of this paper 181. It appears by that article that Mr. Burd turnips at the rate of 760 bushels to an acre, on g which had previously, the same year, produced of clover, rye, wheat, flax and peas."

A hint to Stage owners.—The inconvenience and misery of cold feet, while riding in the winter, is obviated in the North of France, by means of pewter tanks (made the manner of water plates) being fitted to the bottom of the stages, and filled with hot water at each stopping place, which impart not warmth to the feet in the coldest weather, a pleasant glow of heat through the stage, similar to that experienced in a room.

GOOD INK.—From Niles' Register.

The following notice, copied from the "Enquirer," and addressed to the "Councils of justice" in Virginia, involves a matter of great importance to the public; and every one may possess himself of ink that is as good as the best. I republish, from the 17th vol. of "Niles' Register," the following receipt, which was furnished to me by the late Joseph James, who was remarkable for his attention to matters of this nature, and withal a good chemist and exceedingly fond of useful experiments. The character of the ink, made according to his directions, is this—it is very strong and durable, yet flows freely from the pen; it is commonly black, yet dries very quickly.

I repeat, once more, it to be important in the highest degree, that records, (which are to endure for ages,) be written with strong durable ink; and it is much to be regretted that former mild and friendly admonitions on this subject, have had little or no effect. It seems indeed to be progressive and gains

ound, as there has been lately brought to several records from different sections of the State, so obscure as scarcely to be legible, even those whose eyesight remains unimpaired! clerks, who made use of pale ink, for records, were impeached and deprived of their clerkships, for misbehavior in office, a few examples might have a salutary effect, and be beneficial to the community at large.

WILLIAM FLEMING,

President of the Court of Appeals.

Somerville, Sept. 1, 1823.

FROM THE REGISTER, VOL. 17, PAGE 61.

Improved Composition of Black Writing Ink.—Take a gallon of soft water, and boil in it one pound of chips of logwood, for about half an hour, then take the decoction from the fire, and pour it from off the chips, while boiling, hot, on a pound of best Aleppo galls, reduced to a fine powder, and two ounces of pomegranate peels, put into a proper vessel. After stirring them well together, with a wood-spatula, for some time, place them in the sun, in summer, or within the warmth of a fire, if in winter, for three or four days, drying the mixture as often as may be convenient. At the end of that time, add a half pound of green vitriol, powdered, and let the mixture remain for four or five days more, stirring it frequently, and then add further four ounces gum Arabic, dissolved in a quart of boiling water, and after giving the ink some time to settle, strain it off from the dregs, and keep it well stopped for use.

If the ink be desired to shine more, the proportion of the pomegranate peel must be increased; and, in the country where the logwood cannot be so easily obtained, a pound of the privet-berries may be substituted for it.

In order to secure this ink from growing mouldy, a quarter of a pint or more, of spirits of wine may be added; but to prevent its containing any acid, which may injure the ink, a little salt of tartar, or pearl ashes, should be added previously, and the spirit poured off from which will render it innocuous with regard to the color of the ink.

PREPARATION OF SAUR-KRAUT.

Every Russian family, from that of the boor to the nobleman, lays in its stock of cabbage to make Saur-Kraut, about the month of October, before the setting in of the winter frost. It is prepared in the following manner: They take a large strong wooden vessel, or cask, with which every family is furnished, resembling a salt beef cask of the Scotch farmers, and capable of containing as much as is sufficient for the winter's consumption of the family. They then gradually break down or chop the cabbage (deprived entirely of the loose outside leaves) into very small pieces, beginning with one or two cabbages at the bottom of the cask, and adding others at intervals, pressing and rubbing them by means of a wooden spade, against the sides of the cask, until the vessel is nearly full. They then place a heavy weight on the top of it, and allow it to stand near to a peat stove, or any other warm place, for four or five days. By this time it will have undergone fermentation, and be ready for use. Whilst the cabbage is passing through the process of fermentation, a very disagreeably fetid,

acid smell is exhaled from it; and this is strongly perceptible to the olfactory nerves of a person passing near the house, in which the preparation of the Saur-Kraut is going on. They now remove the cask to a cool situation, and keep it always covered up. Aniseeds which are strewed amongst the layers of the cabbage during its preparation, communicate a peculiar flavor to the Saur-Kraut at an after period.

In the boiling of the Saur-Kraut, and preparation of it for the table, two hours are the least period which they allow it to be on the fire. It forms an excellent, nutritious, and antiscorbutic food for winter use. For the greater part of the year, this article, in one form or another, supplies a daily dish to the table of the Russian peasant. It may be made use of as a separate dish by itself, made into soup, or it may be eaten with boiled animal food.

Necessary hints to those who use Copper Vessels for Culinary purposes.

In domestic economy the necessity of keeping copper vessels always clean is generally acknowledged; but it may not perhaps be so generally known, that fat, and other substances, and vegetable acids, do not attack copper while hot; and, therefore, that if no liquid be ever suffered to grow cold in copper vessels, those utensils may be used for every culinary purpose, with perfect safety.

Dr. Johnstone relates the shocking case of three men who died, after excruciating sufferings, in consequence of eating some victuals prepared in an unclean copper on board the Cyclops frigate. Thirty-three other men became ill, and were put upon the sick-list, at the same time, and from the same cause.

Dr. Percival gives an account of a young lady who amused herself, while her hair was dressing, with eating samphire pickle impregnated with copper. She soon complained of pain in the stomach, and in five days vomiting commenced, which was incessant for two days. After this her stomach became prodigiously distended; and in nine days after eating the pickle, death relieved her from her sufferings.

To prevent Lamps from being pernicious to Asthmatic Persons, or others, liable to Complaints of the Chest.

Let a sponge, three or four inches in diameter, be moistened with pure water, and in that state be suspended by a string or wire, exactly over the flame of the lamp, at the distance of a few inches; this substance will absorb all the smoke emitted during the evening, or night, after which it should be rinsed in warm water, by which means it will be again rendered fit for use.

From the American Farmer.

TO PREVENT THE FEMALE BREAST FROM GATHERING.

[Communicated by a Mother.]

Sir—You are a husband and a father, and I greatly mistake your character, if it would not give you particular satisfaction, to communicate in the Farmer, any means of mitigating the sufferings which Mothers experience, in endeavoring to give to their infants from their own breasts, their most congenial and healthful sustenance. There is perhaps in the catalogue

of human pains, none more acute than those which are experienced from the gathering of the female breast, in time of giving suck—pains which too often drive the devoted mother, with heartfelt reluctance, to consign to a strange bosom, the beloved off-spring of her dearest affections, therein relinquishing the most interesting of all her maternal cares and duties, and losing the effect of the most endearing associations, provided by nature, between mother and child. But the faithful wife and the tender mother, only can understand, for she alone can feel the nameless pleasure of imparting to her child in helpless infancy, its chief pleasure, its only nourishment.

None else therefore can estimate the privation. It is for them and their benefit I send you a remedy which I know by experience to be effectual.

To prevent the female breast from gathering or to cure them after they have gathered.

To the yellow of one egg add one table spoonful of brown sugar, one of honey, and one of rum, a small tea spoonful of powdered alum, and as much of rosin, this mixture should be put in a pewter vessel, and mixed well together, then put over a slow fire, and stirred all the time with the finger*, until it comes to a consistency that will spread easily.

A plaster of this spread over the breast before the child is put to them, will prevent their gathering, or should a fever at any time fall in them, a plaster of this salve should immediately be applied, and it will certainly prevent gathering—should matter be formed before the application of the salve, the breast should be kept covered with a thick brown paper made wet with rum, and the salve over the diseased part only; when it breaks, there should be a tent kept in it, and the salve spread on lint, the salve side next the ulcer—the child should be taken from the breast as soon as matter is discovered, which may be done without the least danger of losing the use of the breast, (which is too often the case by the skin cleaving to the bones.)—after the cure is made the child may be allowed to suck, the milk will soon return.

*It must never be made too hot to bear your finger in.

† On lint in order to keep the salve alive.

From the American Farmer.

To the Editor of the American Farmer, or to any person who has any information on the subject.

A dreadful malady has appeared among the cattle in Talbot on two different farms. The animals are seized with a muscular or nervous catching, that resembles hiccoughs, when the complaint seizes them in the head, which it chiefly does; but some have been affected behind, some in one leg, some in the chest, and some across the loins—the catching increases—the part affected is hot and appears to itch so violently, that they soon rub all the hair off, and lacerate the flesh—they appear to have high fever; take to the water; and can be with difficulty kept out of the creeks. They appear constipated, and die in 24 or 36 hours—bleeding, purging, medicine and Antispasmodic balls have been tried without any success.

The Editor solicits the immediate attention of his correspondents to the above, and will busi-

self investigate the subject, by all the means in his power. In the mean time he sends to the gentleman, whose losses dictated the paragraph, the latest treatise on the disorders of cattle, and which he begs him to accept.

The symptoms as here described, seem to indicate a disease arising from some incidental, or local, rather than general or epidemic influence. It is probable, in other words, that some poisonous seeds, or other vegetation are developed at this season, in peculiar places, or by the peculiar weather, to cause such effects; which are in this instance, more conformable to the symptoms of poisonous diet, than those of infected atmosphere. This view is taken from a comparison of the general aspect of symptoms, as described by authors in those two conditions of disease, arising from the one or the other of those sources. The remedy in this case would be, to shut up the cattle, and to treat those affected, by evacuating the stomach and bowels, as quickly as possible, and drenching copiously with mild diluents, as flax seed and melon seed tea—horse radish added, would probably counteract the effect of poisons, in producing cramps, as they usually do, in the stomach and limbs. Any one attentive to these subjects, could readily perceive why a poison taken into the stomach should act differently on the system, from one taken by breathing or infection:—the former disturbing the digestive organs first, and causing some other local affections by their peculiar influence on particular organs—the latter, more generally, causing coldness and fever, debility, thirst, costiveness, &c. before the stomach and brain are much disturbed, being the difference between atmospheric exhalations and poisonous food. If they proceed, even in the present instance, from the former cause, the shutting them up would exclude them from the more direct influence of the cause, morbid exhalation, and besides, would tend to obviate its influence by a more tonic or bracing diet. In either case, the itching and heat of the skin, would indicate a want of transpiration at the surface—or morbid humor thrown there, which the free internal use of sulphur, say one ounce, three or four times a day, would counteract in a warm place, with the flax seed &c. as stated above, especially after the passages were evacuated. The malady is indeed a serious one, as will appear by the following extract to the Editor:—“Since Thursday week, I have lost eight of my grown, and most valuable cattle—my pet cow Europa—5 working oxen and another one of the finest spirited animals that ever bowed his neck to the yoke, is now sick!”

Edit. American Farmer.

Great yield.—Capt. Peter L. Boynton, of Shelburn, in Vermont, raised, the past season, upon three acres and one tenth of an acre of land, two hundred and fifteen bushels of winter wheat. A considerable portion of this crop has been sold for seed at \$1.50 per bushel, averaging from sixty-one and a half to sixty-four pounds per bushel, which is pretty good evidence of its quality. The particular mode of cultivation we have not learnt; but as Mr. Boynton is among the number of our best farmers, presume he pursues the correct one, namely, to use no land than he can cultivate well.

Burlington Sent.

NEW ENGLAND FARMER.

SATURDAY, NOVEMBER 1, 1823.

The subscriber having disposed of the establishment of the New England Farmer to Mr. WILLIAM NICHOLS, requests all persons indebted for the first volume to make immediate payment. Payments for the second volume will be made to Mr. Nichols.

THOMAS W. SHEPARD.

WILLIAM NICHOLS respectfully informs the public that he has purchased the establishment of the New England Farmer, and that it will hereafter be published by him, at the same place, and on the same terms as heretofore by Mr. T. W. Shepard. The paper will be edited as usual by Mr. Fessenden, and no exertion omitted to merit the continuance of that public patronage, which will excite to renewed and unremitting exertion to render it useful to the agricultural community.

OBSERVATIONS ON BEES.

A friend of the Editor states that we may “oblige him and perhaps some others by giving an essay on the best management of bees, with the best mode of extracting the wax, &c.” But we cannot, at present, without omitting some other articles in part or wholly prepared for the paper, which may perhaps prove of equal utility, enter largely into the discussion of this topic, which has occupied the pens of many able and voluminous writers. We will, however, from time to time, offer some intimations on the subject, which we hope will be found little if any less useful than a formal and elaborate treatise.

An article written for the Edinburgh Philosophical Journal by the Rev. Andrew Jameson, states the following mode of constructing Bee-hives, so as to resist the cold of the severest winter. “Let us suppose a hive made of wood, of whatever shape, is 12 inches diameter; then let another hive of the same material be made two, or two and an half inches larger; place the one within the other, and fill the space left by the difference of size with powdered charcoal, hard rammed down; nail a fillet of wood at the bottom to connect the two hives, and to prevent the charcoal from falling out, or damp ascending through the coating, which would destroy in some measure its non-conducting power. The bee door edges must be secured in the same manner. Should charcoal not be to be had, any other non-conductor of heat may be used, as dry saw dust, chopped straw, feathers, &c. but the charcoal is to be preferred, not only as better suited for its most powerfully resisting the transmission of heat, but as less liable to absorb moisture and destroy that power.”

“As the coating prevents the transmission of the internal heat of the insects in summer, this will tend to raise the temperature too high for the health of the bees. This inconvenience may be obviated by a small perforation made through the entire hive at one of the corners, immediately under the projecting part of the roof. To prevent any of the charcoal being moved a tube must be inserted as long as the thickness of the entire hive, a plug made to fit of the same length; and when the ventilation is used, care must be taken that no light is perceptible by the insects, which may be effected either by partially withdrawing the plug, or hanging over the hole at a little distance from the

outside of the hive a piece of black cloth. Perhaps two such ventilating holes may be required; but experience must determine this.”

“The out-side hives may be used merely as cases for the hives which may be in use; removing the cover or caws when any operation is to be performed on the hives.”

The *Complete Farmer's Dictionary* gives the following method of preserving bees in winter, which it appears had been partially tried in England, and may deserve a trial in this country.

“At the usual time of the approach of winter, the hives are removed into a dark vault or cellar; where the bees being kept cold and dark, soon fall into torpid state, and so continue throughout the winter and till the flowers they feed upon begin to be disclosed. They are then removed to their summer situation, and enter upon their labors with great vigor and activity, and having a good stock left of the last year provision, and in no danger of starving, or suffering much by a backward or unfavorable spring, by which other bees are often greatly injured.

“The bees thus removed, are not in much danger from an excess of cold, as that may be moderated in the same manner as is done for preserving wine lodged in vaults in severe winters. The great difficulty seems to be to prevent the bees being too warm in mild winters, which might make them very uneasy and restless, as they are known to be when too much exposed to heat in the summer. Some have proposed as a remedy for this, to place the hives in ice-houses; but this could be of service in a very few places only, and cannot be of general use, if such a degree of cold was necessary, which probably it is not, as the trials which have hitherto made of this method of disposing of bees have succeeded; all their lives, and all their honey also, or much the greater part of it, have been saved.

“Should this method be found effectual upon full experiment, it seems likely to be of more general use than any other hitherto proposed; as it will without doubt be a means of greatly increasing the quantity of wax and honey when it shall be judiciously practised.”

Mistake corrected.—We are informed by a gentleman (to whom we are much indebted for his kindness) that the *PEAR* mentioned in our paper of the 18th ult. page 95, as “a pear from Newryport, weighing 23 1-4 oz.” was brought from Newburyport to Brighton, by Mr. Benjamin Poor. It was raised in the garden of Mr. Joseph George, of Newburyport, and the same tree bore a number of pears this year which weighed 16 ounces and upwards.

Mannoth Turnip.—At the late Cattle Show, an English turnip, raised by the Hon. Oliver Fiske, of this town, was exhibited which weighed with the tops 13 lbs. 4 oz. without the tops 9 lbs. 2 oz. circumference 32½ inches, width 11 inches, thickness 4 inches. It may be seen at Capt. Thomas's bar.—*Worcester Spy.*

An admirable Beverage for a Weak Constitution.—Boil as much pearl, or Scotch barley, in pure water, as will make about three pints, then, straining it off, and, having in the mean time, dissolved an ounce of gum arabic in a little water, mix them, and just boil the whole up together. The barley water need not be thick, as the gum will give it sufficient consistence. When used, take it milk warm; the good effect will soon appear. It must be substituted as a common beverage in place of beer, ale, &c. at meals.

FOREIGN.

at the arrival of the brig *Prudent*, Ellis, on the 29th of this port, in 37 days from Malaga, we learn that French left that place in the night about the 17th of September, and that it was not known where they gone. Nothing was known at Malaga respecting, viz, as all communication between those two places cut off. Capt. E. states that he was in the vicinity of Cadiz several days in light foggy weather, and did a continual firing of cannon. Just before the *Prudent* left Malaga, the American Consul gave to Capt. Ellis a paper, of which the following is a copy.

News has just reached us that Riego after giving them a complete beating in the very streets of Jaén, 700 of them dead besides wounded, proceeded to march and was in a village called La Carolina, daily marching towards Madrid; and was in expectation of joining with Martín, the Empecinado; and little doubt remains that he is at this moment with few leagues of the capital of Spain. The authorities of this place spread a report two days since, that as captured but it was merely to deceive the ignorant and keep alive the hopes of the Serviles, more properly called the Banditti of Spain.

the government of Cadiz remain firm a very short longer, the face of affairs in this unhappy country wear a different aspect, and Europe may have to Spain for saving all the continent from despotism than death.

the conduct of Riego while in this place has been
 ed in the Gibraltar Chronicle in a base and
 ful light, and false in every respect. He acted
 a gallant soldier and a firm and unshaken Patriot,
 mong all the Generals in Spain, he has proved
 lf capable of acting for his unfortunate country in
 ue style of the old Romans."

lost from their neighborhood of Cadiz.—Verbal account from St. Lucar, 12 miles north of Cadiz, to the effect that the French had been received at Portland, by the Pilot, Capt. Hall. No attack on Cadiz had taken place at that time; but requisitions had been sent to St. Lucar for beds, bedding, bandages and the use of those expected to be wounded in attack for which preparations were making. On the 13th it was reported at St. Lucar, that negotiations were in progress, but no success, but the success was not credited by the Constitutionists. It was also reported that the French were repulsed in an attack on the Trocadero the 25th of August, and had 1000 men killed and wounded, but succeeded on the 30th. That the French troops forded the river, in two hand, and drove the Spaniards from the batteries that the former lost 200, and the latter 100 men: it was hinted that \$70,000 helped the surrender. It was further reported, that the French had made an attack on St. Pedro and had 12 gun boats, and a frigate materially injured, and had lost a number of lives.

unts from Vera Cruz, received at N. York, and Sept. 24, assert that all vessels in that port had ordered to leave it, and were getting under way. British sloop Tyne and Bellette were among them. Hostilities between the town and the Castle St. Juan apparently expected to ensue. Preparations were made on both sides; and the Spaniards were flying Juan, the populace having set up the cry of the Europeans.")

DOMESTIC.

Porter arrived at Savannah on the 8th ult. recovering under the effects of the severe illness which he has been afflicted. The other officers now enjoy good health. The Steam Galliot in Com. Porter sailed, left Savannah on the 9th of the Chesapeake.

Providence Journal states, that at the late Convention in Rhode Island, "Dr. Benjamin Dyer, of Providence appeared clad in a complete suit of silk, of fine quality, manufactured in his own family, even to the culture of the trees to the growing of the silkworms producing the material."

rs.—An extensive bed of oysters, said to be of remarkably fine flavor, has been discovered lately, Connecticut river, about five miles above the mouth.

Murder.—Two men, named Andrew Ferguson and Julius Daggert, have been committed for trial to Monroe county Jail, Indiana, charged with having murdered Isaac Edwards, of Lawrence county, in the state of New York. Edwards was pursued by his murderers from a wedding at which they had all been guests. Ferguson and Daggert threatened to slay Edwards, and the latter drew a knife in self defence. The murderers then turned themselves, one with an axe, and the other with a hatchet, and Ferguson struck the deceased with an axe, which penetrated to the brain, and he was satisfied with this, Daggert struck him twice with the club. His death was almost instantaneous.

Convicts at New Orleans.—A desperate attempt was lately made by the convicts in jail in that city to make their escape. As one of the turnkeys was thus making his way to the door, the convicts, who were waiting for opening the inner door of the passage that leads out to the yard, a rush was made upon him, and attempts made to obtain the key of the outer door, which the turnkey prevented by throwing it into the street. An alarm was given, the city guard, a portion of the several volunteer companies, and a large number of citizens immediately assembled, and the prisoners making several attempts to escape, were fired upon—one of the leaders, by the name of Williams, was killed, and another wounded, it is supposed mortally—one other was stabbed in the back, and two slightly wounded.

Gov. Clinton, Benjamin Wright, Esq. and some other scientific gentlemen, are now in New Jersey, traveling and examining the route of the contemplated canal, which is to connect the waters of the Delaware with the Hudson.

Canals.—It is ascertained that the collected waters of the Great Miami and Scioto rivers will not afford a sufficient supply in a dry season, for the purpose of the Ohio Canal. All proceedings are therefore suspended.

Two steam boats, from 1000 to 1200 tons, are building on the St. Lawrence. They are to proceed to England, with cargoes of timber, there to be fitted with Perkins' engines.

Army movements.—We learn from St. Louis, that the six companies of Infantry under the command of Col. Chambers, which arrived at St. Louis from Baton Rouge, moved towards the Council Bluffs on the 12th ultimo, officers and men in fine health. The object of this movement was to sustain Col. Leavenworth in his march against the Rickaree Indians. The intelligence of this conflict with the Rickarees reached St. Louis on the 14th. The detachment moved off, and caused a suspension of its march, which was expected. The detachment would take its winter quarters at Belle Fontaine, where arrangements were making for its accommodation.—*National Intelligence.*

The late JOHN McLEAN, Esq. of this city, has bequeathed *one hundred thousand dollars* to the Massachusetts General Hospital.

The Poultney Gazette mentions, that a merchant in that village, received in one day 13,388 lbs. of Cheese, in another, 10,000; and that about 10,000 more were expected on the third, making 33,333 lbs. or nearly *eighteen tons!*

It is stated in the French *Annales de l'Industrie*, that the *Chestnut tree* bark contains twice as much of the tanning principle as that of oak, and nearly twice as much coloring matter as logwood. With iron it forms an intensely black and durable ink. Its coloring matter has a stronger affinity than Sumach for wool, and is not affected by air or light.

A lady was lately near being killed by a sportsman in England. She was passing on horseback, while he was in the field, and seeing only the feathers of her bonnet above the wall, took her for a bird, and fired.

The Collector of the port of Buffalo, N. Y. seized near that place on the 18th inst. sundry British goods, value about \$1200, which had been smuggled from Canada, and were proceeding eastward *without an owner*, in charge of a teamster. The owners had better have been honest and paid the duties.

The general election in New Jersey has just terminated. The contest has been for those who are for continuing legal interest there at seven per cent, and those who are for reducing it to six. The Six Per Cent party are said to have been successful.

The Rev. Dr. Humphrey was on the 15 inst. inaugurated as President of the Amherst Collegiate Institution. A sermon was preached on the occasion by the Rev. Dr. Storrs, of Braintree, and an inaugural address was delivered by the President. It is said that these discourses are to be published.

NEW ENGLAND FARMER.

FOR sale by WELLS & LULLY, No. 98, Court St. the New England Farmer, or Georgical Dictionary, containing a compendious account of the Ways and Methods in which the important art of *Husbandry*, in all its various branches is, or may be pursued to the greatest advantage in this country. By SAMUEL DEANE, D. D. &c. *Third edition*, corrected, improved, greatly enlarged, and adapted to the present state of Agriculture. Price, neatly bound and lettered, *Two Dollars*.
November 1.

FOR THE NEW ENGLAND FARMER.

SUMMUM BONUM OR MAN'S GREATEST GOOD.

The GREATEST GOOD is every mortal's aim,
The means are various, but the end the same—
Some seek seclusion, some in crowds to share,
Some pant for office, others court the mire;
Some place their happiness in plaintive breath,
And glory wrested from the jaws of death—
Rush to the cannon's mouth to have it said
That hero nobly died in honor's bed!
And some in quest of bliss thir'd pleasure's maze,
The body pamper till the mind decays;
They gratify each gross and grovelling sense
In riot rude or stupid indolence,
As if they meant ingloriously to vie
With the brute habitants of stall and sty;—
And clog at last their animal machine
With gout, dyspepsia, kthargy or spleen.
Some place their greatest happiness in wealth,
To Mammon sacrifice their ease and health—
Conscience, humanity and peace of mind
To hoard up heaps of glittering dust resign'd,
They gain to recompense their toils and cares
Enough to spoil their dissipated heirs—
All these, a wild, miscalculating train,
Seek happiness, but misery obtain.

What then is happiness? aye, what indeed!
No moral doctors have in that agreed,
And metaphysics, with its turns and twists
Ne'er told in what true happiness consists—
Though true it is that Pope said long ago,
"Virtue alone is happiness below,"
Some will believe his definition vain,
When virtue's boon is poverty and pain;
And innocence itself, as one would guess,
Is not quite happy under sore distress,
Virtue, though all important is not all
Which makes what we true happiness should call;
But pure felicity, to all intents,
Is virtue's freedom, peace, health, competence,
Friendship and love—these must kind heaven bestow,
To constitute man's GREATEST GOOD below.

EASY AND EFFECTUAL CURE FOR WENS.

Having had a wen of the stentatomous kind, of large size and long standing upon the side of my face, immediately before and below my right ear, I was informed, by different people, that if I would apply salt and water to it, I should get rid of it. In August, 1799, I put a quantity of salt and water into a sauce pan, and boiled it for four minutes; with which I bathed the surface frequently, while it continued warm as also after it became cold so often as ten or twelve times daily; always stirring up the salt deposited at the bottom of the basin, and incorporating it again with the water before I applied it. On the 11th day from the first application, while shaving, I observed a small discharge, which, assisted by a gentle pressure, the whole contents were soon emptied without the smallest pain and without blood.

Being informed of some others who had been benefited in like manner from the same application, and knowing myself of some late instances, under my own immediate direction, I felt it a duty thus to make it public; being convinced it can produce no bad effect, and every person having it in their power to make the trial. At the same time, I beg leave to caution, that no one should be disheartened at the length of

time it may be necessary to continue the application; as in some cases, it has required three or four months, though in the last only thirty days; but in all without pain or inconvenience of any kind, or any previous notice of the discharge, till it actually took place.

Chisholme, Eng. WM. CHISHOLME.

From the New York Statesman.

CULTIVATION OF THE VINE.

A friend has handed us proposals for publishing, by subscription, a work entitled the *vineyard*; or, the art of cultivating the vine and of making wine; by *William Lee*, for several years Consul for the United States at Bordeaux. This work will be comprised in one volume, of 300 or 350 octavo pages, and contain the history of the vine from the earliest ages—the natural history, and the varieties most generally cultivated—the climate, soil and exposure of the best vineyards in Europe—the choice of plants, manner of planting, and of cultivating the vine—diseases of the vine, accidents, and the manner of preventing both, and of renewing the plants—and the whole process of preserving the fruit, and making wine and vinegar. The whole will form a complete system for conducting a vineyard.

Within the last year, we have had an opportunity of tasting the most delicious wines, made in different parts of the United States; and in the course of the present season, we have seen in two gardens, one at Brooklyn, and the other at West-Point, the strongest proofs that in our climate the grape may be cultivated in the greatest profusion, and of an excellent quality, and with very little labor and expense. There is a single stock growing at Brooklyn, which at this moment bears \$500 worth of grapes, while it has cost the proprietor scarcely as many cents for the cultivation, and at the same time furnished a most delightful arbor during the heat of summer. The vine is from North-Carolina, and so far from degenerating, it appears to be improved by being transplanted to a more northern latitude.

From the Boston Palladium.

Messrs. Editors—I saw in the Palladium, some time since, an account of the Perennial Cabbage, taken from an English paper. Cabbages may be produced from our common Cabbage, in this way. Cut off the stalk near the ground, late in the fall—sprouts will shoot up early in the spring—if they start from above the surface, they are seed sprouts—take them away until others appear from below the surface—leave one, and it will produce an early head. These plants are more likely to withstand the brown worm, than the slender plant from the seed, and are much earlier.

W. N.

R—, Sept. 1823.

Indian sagacity.—Traveling a few years since through that portion of our country held and occupied by the Chickasaw tribe of Indians, I was constrained to halt a few days, to recruit myself and horse at an half breed's hut. When about to depart I sought my host, but he was out hunting. I therefore called upon an old Indian (an inmate of the hut) for my bill. Five dollars was the demand. I presented a bank note for the amount. He refused it; but on my turning

my pockets, and exhibiting the contents of a portmanteau, to shew that I was absolutely destitute of coin—he, with much apparent reluctance, agreed to take the note. He then went out, leaving it in my hands, and shortly returned to my astonishment, bearing a pair of steel-yard. He took the note, compared the figures there with the 5 on the steel-yards, laughed, shook his head with great satisfaction, and cried *che-nah!*—(good—'tis right.)—*Prov. Journal.*

Two gentlemen riding in the country one then observed a handsome seat delightfully situated, and inquired of his companion who it was? who informed him it belonged to a cardmaker. Upon my life said the gentleman, one would imagine all that man's cards turn up trumps.

Com. Decatur in concluding a late treaty peace with the Dey of Algiers, was urged the Dey to pay him some kind of tribute, or if nothing more than a quantity of powder annually. The Commodore observed, that he not doubt his government would have any objection to pay him in powder, but he would have to take balls with it.

Guess work.—When I see a young man possess no more honor than to be dunned, I guess he will never make a man of respectability. When I see a man quit work because he has three or four hired men to oversee, I guess he will have to go to jail to pay them. When I see a man suffer a simple wife to run in debt at the store for whatsoever she fancies, I guess he will wish he had never been married.

When I pass a house and see the yard cove with stumps, old hoops, and broken earthenware, I guess the man is a horse-jockey, and the woman a spinner of street yarn. When I pass a house and see the windows broken, a bundle of straw in one, and a hat in another, I guess the mistress is a slut and the master loves rum. When I see a country merchant hire two clerks to tend store while he sets by the stove, drinking rum, I guess he will soon have to take the benefit of the Insolvent Act, or take a tour to Vernon.

A traveller having put up at a country inn, where a number of neighboring farmers collected, and hearing them tell a number of 'tough stories' about their cattle, sheep, or hogged leaves to offer a short story. A neighbor of his having a sickly sheep, told him out to pasture with perfect indifference brought him in at the fall, fed him attentively for a while—"and how much tallow do you think the sheep had?" "Ten pounds," said one; "fourteen," says another; "twenty," says a third—till they had all become impatient to know the weight of tallow in the extra-rum sheep—when one asked, "how much tallow did he have?" "I don't know," replied the stranger, "but I guess not much."

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at discretion of the Publisher) until arrearages are paid.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

REMARKS ON PLOUGHING.

Although we have in the first volume of this work, pages 60, 278, 393, treated on this subject, we further observations on the most important operation of agriculture may, perhaps, be beneficial, to practical farmers, by furnishing hints, and suggesting ideas which may lead to a train of investigation terminating in results of importance.

To all stiff, heavy and adhesive soils, that are clogged with moisture, it should be a common rule not to plough them while wet in any considerable degree, especially if there is much water in their composition. When such land is ploughed wet, the particles of which it is composed are apt to cake, or run together into lumps, which require much trouble and labour to reduce to a fine state. Besides, much injury is produced by the treading of the team, and greater power is necessary in performing the operation. But, on the other hand, such soils are ploughed with much difficulty, when they are dry; unless before the ploughing they are in a state of tillage, and not baked or set down very hard. To break up grass-land composed of a strong loam, or a soil in which there is clay in any considerable quantity, when in a dry state, is next to impossible. You will almost as well attempt to plough up a brick pavement, or slate rock. Green sward, in general, can hardly be ploughed too wet, if it be not miry. Marshy, moory, and peaty or mossy descriptions of soil, should in general, be already reduced to a state of tillage, before being ploughed when the season is dry.

In dry, sandy, and perhaps, in some of the mellow kinds of loamy soils, the business of ploughing may be performed when the earth is in a state of considerable moisture. But in very sandy land, whenever the weather is hot and dry, should merely be stirred in such a way as may be necessary to prevent the growth of weeds; otherwise the great exhalation of moisture in such seasons may render them too dry for the vigorous vegetation of the seeds or plants, which may be sown or growing upon them. The cultivators of this kind of soil have, therefore, many advantages over others who are engaged in the more stiff and heavy sorts of soil, in being able to perform the various operations of arable husbandry with much less strength and expense of team, and by being less interrupted by the wetness of the seasons. Still clayey soils, which are already broken by the plough, may be beneficially ploughed in dry weather, and it is said that stirring such soils in a dry season, causes them to imbibe moisture, but in sandy soils the opposite result is produced by the same means.

It is very fashionable, and as a general rule, is correct to recommend deep ploughing. This rule has a great many exceptions, and the cultivator, who should be governed by it without regard to the nature of the soil, and the nature of the crops, would only labour hard to injure his land, and reduce his products. We

have already in vol. i. page 60, given "Maxims respecting the proper depth of ploughing," and "Advantages of deep ploughing." It may not be amiss to attend to what some writers have observed respecting the dangers and disadvantages, which attend ploughing deep without regard to the nature of the soil and other circumstances. It is observed in Dickson's Agriculture that "though deep ploughing has been recommended by some modern writers upon particular kinds of land, where the bottom and top were of two opposite qualities, and neither of them perfectly good, that a mixture may sometimes be very beneficial, and the experiment of going below the common depth sometimes answer. But that when the top and bottom for eighteen or twenty inches depth consists of the same soil, it is not believed it is ever worth while to exchange the upper part, which has been enriched for centuries back, for a part less rich, merely because it is more fresh. On retentive soils, where the practice of loosening them to some depth by other implements is omitted, deep ploughing is, however, extremely necessary."

In an "Essay on the best Means of converting Grass Lands into Tillage, by James Roper Esq., published in *Communications to the Board of Agriculture*, vol. iii. page 346, it is observed that "it seems reasonable to prefer light to heavy ploughing, because, all things being equal, it must be preferable to have a small depth of soil to cultivate and improve, and inasmuch as the fibres of grass in general are fed from the upper surface of the earth alone, if they find sufficient pabulum; all that lie underneath their nourishment, and has been with much labour moved by the plough, is like a stock in trade, which requires an extra capital, unproductive of interest.

"I have endeavoured by all means to search into the nature of sainfoin, clover, and lucerne, and the result of my opinion has been that the long penetrating tap roots of these grasses pierce the earth in search of moisture only; that the tap root is the mere syphon and duct; that the branches of the crown of the plant are fed alone by the upper surface of the soil; and that the luxuriance of their produce depends not upon the congeniality of the bed or *nidus* [nest] of the tap root itself; but on the congeniality of the soil of the upper surface, which alone feeds and furnishes it vegetation."

An article in "Communications to the Board of Agriculture" vol. iv. page 147, written by John M. Mardo, Esq. contains the following statement. "We have witnessed instances where old pasture lands, composed of a gravelly loam were broken up in the spring for barley by trench ploughing. The old sward was turned into the bottom of the furrow, and a dry subsoil brought to the surface from a considerable depth. The crops failed entirely, and there appeared two very obvious reasons for the failure; first, the subsoil brought to the surface to form the seed bed had long been deprived of the ordinary influence of the atmosphere, and the rains; consequently must have been cold and infertile. Secondly, the dry tenacious sward

having been placed half broken under the seed bed, the natural moisture of the ground, as well as that which falls in rain, was speedily and habitually evaporated; unless in a season of uncommon moisture, a crop under such preparation could not prosper."

A writer in the General Report of Scotland, Mr. James Brownhill, says "Old Leas, [grass-grounds] in my opinion should be ploughed if possible not above $4\frac{1}{2}$ inches deep by $2\frac{1}{2}$ or 9 inches broad. If the old lea be a dry soil, it will plough very well with those dimensions; if it be ploughed deeper it must also be ploughed broader, as the furrows will not ply close to one another, unless you have breadth in proportion to the depth."

Sir John Sinclair speaks highly of the advantages of deep ploughing in some circumstances and for some crops, but says "it is a general rule never to plough so deep as to penetrate below the soil that was formerly manured and cultivated excepting upon fallow, and then only, when you have plenty of lime or dung to add to, and improve the new soil." The farmers of Flanders, which is said to be the best cultivated part of Europe, gradually deepen their soil by ploughing or digging up fresh earth, as their manure increases. Mr. Arthur Young likewise observes that in poor hungry soils some proportion ought to be observed between the depth of a ploughing and the quantity of manure annually spread. The same writer informs us that the depth of ploughing in various towns of England, on an average in sandy soils was four inches; in loamy soils three and a half, and in clayey soils three inches and a half. But a note in Sir John Sinclair's "Code of Agriculture" informs that "Mr. Parker of Munden, prefers nine inches for the depth of ploughing, and he has practised that system for many years, on good loamy land in Huntingdonshire, as well as in the clays and flints of Hertfordshire. He never lost a crop by it, but has met with unvaried success; and he is clearly of opinion, that the propriety of deep ploughing ought not to be made a question, but received as an admitted truth. The farming gardeners near London, act upon the same system with great success. They plough to the depth of from ten to twelve inches, for cabbages and other crops, with implements made on purpose, and with from six to eight powerful horses. Mr. Marshall has known a succession of shallow ploughing farmers beggared on a stiff land farm; and their successors by deeper tillage, make a farmer's fortune upon it."

We have heretofore, vol. i. page 278, given some remarks on the advantages of Fall Ploughing, and showed wherein it was in general to be preferred to ploughing in the spring. We shall add nothing at this time, to that part of our subject, but hope our agricultural readers will attend to *Horizontal Ploughing*. In page 14, of our first volume we have given an article on the subject of drawing horizontal or perfectly level furrows on hilly lands, and given a cut of the rafter level; or implement introduced into Virginia by Col. Randolph, son in law to Mr. Jefferson.

Whether the rafter level has yet been introduced in this part of the United States, we cannot say, although we are informed that it is a very common implement of agriculture in Virginia. Those who do not like to try a new thing, may perhaps, derive some advantage from the following observations on horizontal ploughing copied from *Dean's New England Farmer*.

"Regard should be had to the shape of the land in ploughing. They who plough a steep hill up and down injure their cattle, and miss of ploughing their land to advantage. The furrow that is drawn up hill must be excessively shoal; or the team much stronger than common. For this reason a hill should be ploughed horizontally, with rows as nearly parallel to the base as possible. This may be easily done when all the sides of a hill are to be ploughed at once. The rains will carry much of the finest of the soil to the bottom of the hill if the furrows are made up and down. But ploughed the other way the furrows will be sufficient drains; and the water will move so slowly in them that none of the soil will be washed away. But when a hill is very steep, no turning of a furrow upwards should be attempted. And if only one side of a steep hill is to be ploughed, the furrows should be all cut the same way, the team returning light after each furrow."

(TO BE CONTINUED.)

CATTLE SHOWS.

The fourth Annual Cattle Show, and Exhibition of the Rhode Island Society for the Encouragement of Domestic Industry was held at Pawtuxet, on the 15th and 16th of October, 1823. The Committee for the examination of Live Stock, and awarding premiums thereon (Hon. Tristram Burgess, Chairman,) made a report, from which the following is extracted:

"The general appearance of the stock was highly satisfactory, and strongly indicated the progress of improvement. The committee know how much all the success of farming depends on the animals propagated and reared for agricultural purposes. They are in a manner associated with us in the toils of the fields, and contribute greatly to all our household comforts—the skilful farmer realizes the strength of the ox and accommodates himself with the speed of the horse; and the other animals raised by his care and skill, and fed from his hand, reward him with food and clothing, and give to his habitation some of its best ornaments and most commodious luxuries. It is not needful for us to remind such a man how much of all this depends on the care and skill with which he makes his selections among the various breeds of domestic animals which have been offered to his choice by a bountiful Providence. Much indeed depends on feeding, but more perhaps, on the animal chosen for that purpose; and we can sometimes almost realize the dream of the Egyptian monarch in reviewing the cattle of two different farmers. It is a principle in the branch of agricultural economy, that those animals should be sought after by the farmer which will give him the most in return for the least received of him. In awarding the premiums offered by the society, the committee have been governed by this principle. They are gratified with the emulation of all their farming brethren who have entered into this competition so highly

beneficial to the best interests of the community."

Then follows a list of the premiums, which is too long for insertion.

The committee on *Shop Manufactures* observed that "they were much pleased with a model of a newly invented Spinning Machine, called the "Balance Flyer Throstle," presented by Mr. E. Fuller, of Cranston. This Machine has the appearance of being a valuable and important improvement in spinning cotton, particularly of slack twisted yarns. They have awarded him the Society's certificate of approbation and withheld the premium, there being no competition."

Among the Household Manufactures for which premiums were awarded were Imitation Leghorn Bonnets, Straw Bonnets, Carpeting, Hose, Flannels, Counterpanes, a Sampler, Map of the United States by Anne Calden, of Providence, Fancy Shell Baskets, Picture Drawing—one Trunk, containing Fancy Articles by the Young Ladies' Academy, Providence, Net Curtains, &c. &c.

"The Committee were highly gratified at seeing Dr. Benjamin Dyer, of Providence, clad in a complete suit of silk of a superior quality, manufactured in his own family, even from the culture of the trees to the growing of the worms, producing the material. Such exertions to independence in our manufactures, in this article, by this spirited individual, not only deserves the praise and approbation of the committee, but merits the applause of the public."

Premiums were likewise awarded on Mill Manufactures and on Ploughing. A pair of three years old steers, owned and driven by Mr. Nicholas Waterman, of Johnston, "ploughed one eighth of an acre of ground, well, in the short space of 15 minutes and 50 seconds." The exhibition of draught oxen was highly commended by the Committee.—*Abridged from the Farmers' and Manufacturers' Journal.*

The Bristol County Agricultural Society held its first annual Exhibition in Taunton, Oct. 21 and 22, 1823. A variety of articles, in the department of manufactures, wrought in families and in manufacturing establishments was exhibited, together with live animals, and the products of the soil and the dairy and excited the surprise and delight of the most sanguine well-wishers of the Society. At 12 o'clock, an appropriate prayer by the Rev. Mr. Hamilton, an elegant and instructive address, by the Hon. Francis Baylies, and very excellent music formed the exercises at the Meeting House of the First Congregational Society. After the address the Society formed a procession, which repaired to Mr. Atwood's Hotel, where, with invited guests they partook of an excellent dinner. In the afternoon the several Committees on Manufactures, Agricultural Products and Animals, prepared their Reports, which were announced on the following day in the Meeting House. On the second day, in the afternoon, the Ploughing Match took place near the Academy, witnessed by a vast number of delighted spectators.—Three teams, of one yoke each, entered the field, and ploughed one eighth of an acre each, in as short a time, considering the hardness of the sward through which the plough passed, as the annals of ploughing matches in this country have ever reached—and the neatness of the

work, as well as the expertness of the performer, gained the warmest applause of the committee and many experienced farmers present. Immediately after the ploughing match there was an auction of some animals, in the Hall of the Society. Among the *Domestic Manufactures* which received premiums were the following articles:—Cotton Sheetting, Cotton Shirting, Si net, Carpeting, Hearth Rugs, Cotton and Woolen Flannel, an Imitation Leghorn Bonnet, Straw Bonnets, Boots, Calf skins, a Beaver Hat Plough, an Axe, Rose Blankets, Sewing Cotton a Bit-Stock and Bit, Shovels and Weavers' Shutes, Linen Sheetting and Shirting.

The following articles were recommended as entitled to *Certificates of Excellence*: a beautiful quilted Counterpane, fine specimens of cotton and linen Diaper, a beautiful shell work Basket, Hearth Rugs and Calf skin Boots. *Agricultural Products* were mostly of the usual kinds excepting fine specimens of peach and apple trees, produced by inoculation the present season, by Jacob Dean, of Mansfield, a Potatoes produced from the seed of the present season, some of them as large as hen's eggs, James P. Lyon. The time in which Ploughing was completed was as follows: A ner Thayer one eighth of an acre in twenty minutes, Samuel Crocker, twenty-three minutes, and Samuel Robertson, twenty-three minutes.

Officers of the Bristol County Agricultural Society for the ensuing year.

Hon. Samuel Crocker, Taunton, President. Hon. Oliver Starkweather, Seekonk, Rev. P. Clark, Norton, Rev. Otis Thompson, Rehoboth and Thomas Ahmy, Esq. Dartmouth, Vice Presidents; Dea. Peter Thacher, Attleborough Treasurer; Horatio Leonard, Esq. Raynha Recording Secretary; Hon. James L. Hodges, Taunton, Corresponding Secretary.

Committee on Agriculture.—Roland Howar Esq. Easton; Lemuel May, Esq. Attleborough Mr. Enos Williams, Raynham; Capt. She Weaver, Troy; Mr. Jesse Smith, Taunton.

Committee on Domestic Animals.—George V. Peck, Esq. Rehoboth; Mr. George W. Walke Seekonk; Mr. Fardon Cornell, Dartmouth; M. Dan Wilmath, Taunton; Mr. William Rea Somerset.

Committee on Domestic Manufactures.—Joseph E. Read, Esq. Troy; Nath'l Wheeler, Esq. W.ington; Solomon Pratt, Esq. Mansfield; Abiath Richardson, Esq. Attleborough; Mr. Hen Washburn, Taunton.

Committee of Publication.—Hon. Francis Baylies, Hon. James L. Hodges, David G. W. Cobb Esq. all of Taunton.

From the Boston Commercial Gazette.

CIRCULAR.

SIR,—On the 19th of October last (the second day of the annual Fair in this vicinity) a meeting was held of the Manufacturers of Woollens in Massachusetts, to consider the subject of petitioning Congress to increase the duties on woollens. At this meeting, Hon. JESSE PUTNAM, president, and Mr. J. B. Brown was Secretary. The subject was discussed, and a vote passed that it was the opinion of the meeting that an application ought to be made to the national legislature, to revise the Tariff, and to increase the duties on foreign woollen goods. A commi

of five persons was thereupon chosen to report a petition. In the course of the evening a petition was reported, read, discussed, and accepted by a unanimous vote. This petition, signed by the Chairman, and attested by the secretary, will be forwarded to Congress by one of the representatives of this state. At the same meeting, a Committee was appointed to correspond with manufacturers in different parts of the Union, in order to induce their co-operation in measure deemed so highly important to them and to the general interests of the country. In pursuance of this vote, the Committee beg leave to present to you their views of the subject.

The Manufacturers of this state disclaim all pretensions to exclusive privileges, and desire only a reasonable participation in the prosperity of their fellow-citizens. They would advance aims no farther than they are in harmony with the general welfare, and tend to promote the present and future well being of the country. The idle clamor of interested persons may continue, but the unfounded jealousies of other great interests have, it is believed, abated, and the true sentiment of the identity of the agricultural and manufacturing classes, generally prevails. The depressed condition of the woolen manufactures of this country, at the present time, is well known. Several have been compelled to suspend or change their operations; others are apprehensive of a similar fate; and all are persuaded that a moderate increase of impost on foreign manufactures of wool, will revive and sustain their establishments. While petitioning for such relief, it is our bounden duty to show the necessity and reasonableness of our request.

The following axioms may be considered as established by the concurrent voice of a large majority of the citizens of this country:—The people, possessing, by the bounty of heaven, adequate capital, necessary materials, and requisite skill, are destined to become a manufacturing, as well as a commercial and agricultural nation; employment in this occupation is congenial with the morals, health, intelligence and accumulation of property, of the citizens; the rate of Duties on foreign merchandises should be increased in proportion to the growing ability of this country to supply its internal consumption; a Tariff should be framed to protect manufacturers, as well as to provide for a revenue; existing manufacturing establishments are to be sustained to render us independent of foreign nations, and they can be protected only by government.

Protection, then is all manufacturers ask; and we believe a moderate increase of duties adequate to this purpose, without prohibiting the exportation of woollen goods. We concede at duties amounting to a prohibition would be necessary and unsafe. A sudden and unnatural increase of manufactures would ensue; a great wound would thus be given to this branch of national industry, eventually detrimental to the recipients of it, and the demands of the country could not be immediately supplied by them. Placed upon equal footing with foreign competitors, we doubt not the enlightened people of this country will give a preference to the fabrics of their own countrymen.

Owing to various causes, we are unable to compete with foreign nations in supplying our market with woollen goods. Their machinery is

more perfect, the wages of labor are less, and wool is more abundant and is cheaper. British cloths are selling at a profit, while American cloths yield little, if any, to the manufacturer. It is the policy and intention of foreign governments further to cripple, and if practicable, to paralyze the manufacturing establishments of this country. Their eminent Statesmen have openly and strenuously recommended making great sacrifices to attain this object. It is now contemplated, in England, to allow a drawback on manufactures of foreign wool, which will be equivalent to twelve and a half per centum on coarse fabrics.

Raising the duties on foreign woollen goods will tend to increase the growth of wool in this country. An early adoption of this salutary measure would have prevented the destruction of valuable sheep. Efficient interposition, at this time, by Congress, will stimulate the agricultural interest to improve and increase their flocks, in which this nation is greatly deficient. While in England the native wool composes a large share of the quantity manufactured, the United States depends upon a foreign country for a great proportion of its supply.

We contend that an increase of duties will not be injurious to the great body of the people by manufacturers exacting exorbitant prices for their goods. We believe the permanent interests of all classes of the community are promoted by such moderate gains as will insure industry, prudence and perseverance, and are fully convinced that "the internal competition which takes place soon does away every thing like monopoly, and reduces by degrees the price to the minimum of a reasonable profit on the capital employed." The experience of this country establishes the truth of this position. Notwithstanding the Tariff of 1816 imposed prohibitory duties on low cottons, they are now sold at half their former prices, considering the relative value of the fabrics; and it is not doubted but the fostering care of government over manufactures of woollens would tend to improve their quality, while it would eventually reduce their price. Government has incurred an obligation to cherish the manufacturing interests of the country, as during the late war, when great inconvenience was experienced by want of necessary supplies of clothing for the army, strong inducements were held out to their constituents to render the nation independent of foreign countries for clothing.—Extensive and numerous establishments were made, in the confident expectation that they would not be suffered to languish for want of the continued protection of government.

We contend, also, that the increase of duties will not impair the revenue of the U. States.—It was predicted by the opposers of the prohibitory Tariff of 1816, that the importations of India cottons, would lessen the resources of the Treasury to an alarming amount. These predictions have not been fulfilled. The increase of our population, the artificial wants of the inhabitants, and the greater ability to purchase, will, it is presumed, ever continue a demand for the fabrics of other nations; the wise governments of the old world will lend their powerful aid, as hitherto, in enabling their subjects to rival the youthful establishments of this country; and it cannot be denied that "the interests of the revenue are promoted by what-

ever promotes an increase of national industry and wealth."

In the petition referred to we have requested an addition of *twelve and a half per cent*, on all manufactures of foreign wool, together with a further countervailing duty, should the contemplated drawback on British manufactures be granted by the government of that country, or any increase of impost be deemed expedient on the importations of wool into the United States.

We have thus expressed, at length, our ideas on this important subject, and the co-operation of Manufacturers, in bringing the subject before Congress, and presenting it in a candid light to the consideration of our fellow citizens engaged in other pursuits, is earnestly recommended.

I have the honor to be, respectfully,

Your obedient servant,

JOSHUA CLAPP.

Chairman of Committee of Correspondence.

Ladies' Apparel.—Last evening we had the pleasure of examining some of the most beautiful specimens of the industry and taste of our fair countrywomen that we have ever seen.—Two bonnets and two vandykes, one of each wrought by Mrs. Keyes, and the others by Miss Collar, both of Sangerfield, Oneida county, were sent to our office for inspection, and for exhibition and sale at the Mount Vernon Fair. They are made of the finest down of the milk weed, in fashionable form, lined with white silk, and are as rich flowing and elegant as if composed of floss silk. We have no doubt they will attract the particular attention of the ladies, and we shall be disappointed if there is not considerable competition among patriotic husbands in bidding at the auction for these beautiful articles of dress for their wives, as well as by way of rewarding the ladies who have wrought them with so much skill, and sent them hither in the hope of fair compensation and encouragement to renewed efforts. The Fair in this county is considered the most important in the state, and the show of manufactures, particularly household productions, is the best and most various, with the exception, perhaps, of Brighton Fair, of any in this country. We hope the sale of the articles exhibited will stimulate to further improvement. [N. Y. Statesman.

A little girl who was matched to walk 30 miles in eight hours and a half, accomplished her task on Monday week, in a quarter of a mile circle, on Pennenden Heath. She performed the distance, with apparent ease in 7 hours 57 minutes having 33 minutes to spare. The weather was particularly unfavorable for her, it raining heavily a great part of the time. Her name is Emma Matilda Freeman; she resides at Strond, and is scarcely eight years of age.

Eng. Paper.

Beet.—A correspondent in Belchertown, informs us that Mr. John Robbins of that town, made him a present, the last spring of a blood beet, which he raised the year before, and which weighed 25 pounds 8 oz. He says—"Let Middlefield gardeners try again."—Hamp. Gaz.

Coal discovered.—The Lehigh Company of Philadelphia has discovered a large body of Coal within a mile and an half of the river.—the coal now brought to market has to be transported nine miles by land.

From the London Horticultural Transactions.

On the Native Country of the Wild Potatoe, with an account of its Culture in the Garden of the Horticultural Society; and Observations on the Importance of obtaining improved Varieties of the Cultivated Plant. By Joseph Sabine, Esq. F. R. S. &c.

The possession of the plants of the *Native Wild Potatoe*, has been long a desideratum, and from the great importance and extensive use of the cultivated root, the subject of course became an object of attention to the Horticultural Society. In my communications with the Society's correspondents on the other side of the Atlantic, this was pointed out as one of the most interesting objects to which their attention could be directed; and it is with no small satisfaction that I am able to state that our inquiries have been successful.

Great doubts have existed as to what parts of the new world the natural habitat of the *Solanum tuberosum* or *Potatoe* should be assigned; and the question is even now a matter of discussion among Botanists of the greatest eminence. The vegetable, in its cultivated state, was first known in this country as the *Potatoe* of Virginia; I conceive, however, there can be little doubt that the plants which Sir Walter Raleigh found in that colony, and transferred to Ireland, had been previously introduced there from some of the Spanish territories, in the more southern parts of that quarter of the globe; for had the *potatoe* been a native of any district, now forming part of the United States, it would before this time have been found and recognised by the botanical collectors who have traversed and examined those countries.

From the Baron de Humboldt's observations on the *potatoe* in Mexico, it seems certain that it is not wild in the southwestern part of North America; nor is it known otherwise than as a garden plant in any of the West India islands.—Its existence, therefore, remains to be fixed in South America, and it seems now satisfactorily proved, that it is to be found both in elevated places in the tropical regions, and in the more temperate districts on the western coasts of the southern part of that division of the new world.

According to Molina, it grows wild abundantly in the fields of Chili, and in its natural state is called by the natives *Muglia*, producing, when uncultivated, small and bitter tubers. The Baron de Humboldt asserts, that it is not indigenous in Peru, nor in any part of the Cordilleras situated under the tropics. But this statement is contradicted by M. Lambert, on the authority of Don Francisco Zen; the former of whom says, that he and his companions Dombey and Ruiz, had not only gathered the *Solanum tuberosum* wild in Chili, but also in Peru, in the environs of Lima; and the latter has assured Mr. Lambert, that he had found it growing in the forests near Santa Fe de Bogota. The above account of Pavon is further confirmed by the evidence of a specimen gathered by him in Peru, and now forming a part of the herbarium of Mr. Lambert, with the name of "*Patatas del Peru*."

Mr. Lambert, in his communications to the *Journal of Science and the Arts*, supposes that the wild *potatoe* is to be found in the eastern, as well as the western and northern sides of South America. His opinion on this point ap-

pears to have been founded on the following circumstances:

Among the specimens in the Herbarium formed by Commerson, when he accompanied Bougainville in his voyage round the world, is one of a *Solanum*, gathered near Monte Video. In the *Supplement to the Encyclopedie*, this specimen was described, on the authority of M. Dunal, of Montpellier, as belonging to a species distinct from *Solanum tuberosum*, under the name of *Solanum Commersonii*, and it was subsequently published by M. Dunal, with the same name in the *Supplement to his Solanum Synopsis*. Mr. Lambert, however, conjectured this specimen to be that of the type of the cultivated *potatoe*, and was induced to do so by information received from Mr. Baldwin, an American botanist, that he had found the *Solanum tuberosum* wild, both at Monte, and in the vicinity of Maldonado, as well as from Captain Bowles, who had resided a considerable time at Buenos Ayres, and who had told him that this plant was a common weed in the gardens and neighborhood of Monte Video.

The above statements certainly confirm the existence of a plant in sufficient abundance near the shores of the Rio de la Plata, which Mr. Lambert identifies with Commerson's specimen; but the proof that it is the *Solanum tuberosum*, in opposition to the decision of M. Dunal, rests only on the opinion of Dr. Baldwin, and Capt. Bowles, without the usual satisfactory evidence of specimens, which have not been supplied by either of these gentlemen.

In order to elucidate the question as much as possible, I applied to M. Desfontaines, Director of the Museum of Natural History in the Jardin du Roi at Paris, for permission to have a drawing made of Commerson's original specimen, which was deposited in the Herbarium under his charge. With a liberality and kindness which I cannot too highly compliment, the entire specimen was, without delay transmitted to me. It has much the appearance of being in a dwarf or stunted state. The label affixed to it is thus described: "*Hispanis Tomates—dores sunt pallidius—de la plage du pied du morne de Monte Video en Mai, 1797.*" The size of the blossom is evidently larger than that of the *S. tuberosum*, under similar circumstances; the depths of the divisions of the flowers, and the large proportional size of the terminal leaf, present striking differences from correspondent parts of the common *potatoe*. Very little hairiness is perceptible on the specimen, which if it had been taken from a plant of *S. tuberosum*, would probably have been much more hairy, as it usually is when stunted. It is also somewhat singular that Commerson, who could not but know the *S. tuberosum* and its various names, should have affixed that of "*Tomates*" to his specimen; this makes it almost certain that he did not consider it to be the *potatoe*. On these grounds I have ventured to hesitate in concurring in the opinion of M. Lambert, that we have sufficient evidence of the growth of the wild *potatoe* in the neighborhood of the Rio de La Plata. It possibly may be found there, but its existence in that part of America is not proved, since it seems tolerably certain that Commerson's plant is not it, and M. Lambert does not suppose that the plants seen by his correspondent and friend were different from Commerson's.

Early in the spring of the present year Mr.

Caldcleugh, who had been some time resident at Rio Janeiro, in the situation of secretary to the British Minister at that Court, where I had been indefatigable in his exertions to forward the objects of the Horticultural Society, returned to England, having previously taken journey across the country, and visited the principal places on the western coast of South America. Among many articles of curiosity which he brought with him, were two tubers of the wild *potatoe*, which he sent to me with the following letter:

Montague Place, Portman Square,
February 24, 1823.

MY DEAR SIR—It is with no small degree of pleasure that I am enabled to send you some specimens of the *Solanum tuberosum*, or *Native Wild Potatoe* of South America.

It is found growing in considerable quantities in ravines in the immediate neighborhood of Valparaiso on the western side of South America, in lat. 34, 30, S. The leaves and flower of the plant are similar in every respect to those cultivated in England, and elsewhere. It begins to flower in the month of October, the spring of that climate, and is not very prolific. The roots are small and of a bitterish taste some with red and others with yellowish skins. I am inclined to think that the plant grows to a large extent of the coast, for in the south of Chili it is found and called by the natives *Magalia*, but I cannot discover that it is employed to any purpose.

I am indebted for these specimens to an officer of His Majesty's ship *Owen Glendower*, who left the country some time after me.

ALEXANDER CALDCLEUGH.

The two tubers were exhibited to the Society, and a drawing made of them before they were planted. Had there been a third, I should have been tempted to have satisfied myself as to the real flavor, which Mr. Caldcleugh, as well as Molina, describes as bitter. They were planted separately in small pots, and speedily vegetated; and grew rapidly, and were subsequently turned out into a border about two feet distance from each other, when they became very strong and luxuriant. The blossoms at first were but sparingly produced, but as the plants were earthed up they increased in vigor, and then bore flowers abundantly; but these were not succeeded by fruit. The flower was white, and differed in no respect from those varieties of the common *potatoe* which have white blossoms. The leaves were compared with several varieties of the cultivated *potatoe*, which generally were rather of a more rugose & uneven surface above, and with the veins stronger and more conspicuous below, but in other respects there was no difference between them. The pinnule which grew on the sides of the petiole, between the pinnæ of the leaves, were few, not near so numerous as in some varieties of the cultivated *potatoe*; but in specimens of other varieties that were examined, their leaves were destitute of pinnule, so that the existence of these appendages does not appear to be so essential a characteristic as has been supposed, and as it is stated in the *Supplement to the Encyclopedie*.

The earth with which the plants had been moulded up had been applied in considerable quantity, so as to form a ridge, the sides of

which were full two feet high; and about the 15th of August, runners from the roots and stems of the covered stems protruded themselves towards the surface of the ridge in great numbers, and when they reached the light, formed considerable stems, bearing leaves and tubers, so that at length the two plants became one mass of many apparently different stems issuing from all sides of the ridge. The variance of these runners in such quantities need a doubt as to the identity of the plants. Our common potatoe, which doubt was increased when it was ascertained, that so late as the month of August no tubers had been formed by the roots. The runners were, however, otherwise different from what are formed by cultivated potatoe under ground, except that they were more vigorous, as well as more numerous.

The plants have recently been taken up, and doubt respecting them is now removed; are undoubtedly the *Solanum tuberosum*. The principal stems when extended, measured more than seven feet in length; the produce most abundant, above six hundred tubers gathered from two plants; they are of various sizes, a few as large, or larger than an egg, others as small as the original rather angular, but more globular than others; some are white, others marked with stripes of pale red or white. The flavor of the tubers when boiled, was exactly that of a young potatoe.

The compost used in moulding up the plants, was very much saturated with manure, and to this circumstance I attribute the excessive luxuriance of the growth of the stems; had common garden mould been employed, they would have probably grown so strong, and I suspect while the plants were thus rapidly growing stems and leaves, the formation of the tubers was delayed, for the production of these is the main work of the latter part of the season; they cannot be called fully ripe, nor have they reached the size which they probably might have done if they had been formed earlier.

They will, however, answer perfectly for the purpose of reproduction (or seed, as it is technically called,) and they are in sufficient quantity to be subjected to treatment similar to a common crop of potatoe. The result of another year's experience is necessary to enable us to observe on the merits and value of this introduction; but the following changes already appear to have attended its subjection to cultivation;—the produce is most abundant, the tubers have lost all the bitterness of flavor which is attributed to them in the natural state, their size is increased remarkably; from all these circumstances I am disposed to infer, that the original cultivators of this vegetable did not exercise either much art or patience in the production of their garden potatoe.

The increased growth of the potatoe, not only in these kingdoms, but in almost every civilized part of the globe, has so added to its importance, that any information respecting it has become valuable; the subject of this communication may therefore not be without interest. In the exception of wheat and rice, it is now nearly the vegetable most employed as the staff of man; and it is probable that the period is not far distant, when its extensive use will even place it before those which have

hitherto been considered the chief staples of life. The effect of the unlimited extent to which its cultivation may be carried, on the human race, must be a subject of deep interest to the political economist. The extension of population will be as unbounded as the production of food, which is capable of being produced in very small space, and with great facility; and the increased number of inhabitants of the earth will necessarily induce changes, not only in the political systems, but in all the artificial relations of civilized life. How far such changes may conduce to, or increase the happiness of mankind, is very problematical; more especially when it is considered, that since the potatoe, when in cultivation, is very liable to injury from casualties of season, and that it is not at present known how to keep it in store for use beyond a few months, a general failure of the year's crop, whenever it shall have become the chief or sole support of a country, must inevitably lead to all the misery of famine, more dreadful in proportion to the numbers exposed to its ravages.

Under such circumstances, and with such a prospect, it is surely a paramount duty of those who have the means and power of attending to the subject, to exert themselves in selecting and obtaining varieties of potatoe, not only with superior qualities in flavor and productiveness, but which shall be less subject to injury by changes of weather when in growth, and which may possess the quality of keeping for a length of time, either in their natural state, or under the operation of artificial treatment. This is one of the objects to which the care and energies of the Horticultural Society ought to be directed. Under its auspices, and by its means, some new kinds have been brought into notice, but a wide field of exertion is still before it.—With the potatoe cultivated in South America at the present time, we are very little acquainted; there is one especially which has been heard of, but which has not yet reached us, known at Lima as the yellow or golden potatoe, and which is reported to be far superior in flavor to any now grown in Europe.

On the subject of the potatoe there is also a point of much curiosity and much interest open to those who have leisure and opportunity of conducting the investigation. Several accounts of its introduction into Europe, and especially into Great Britain and Ireland, are before the public, differing from each other, and none exactly correct; the entire truth is probably to be extracted from the whole, and ought to be supported by references to the original authorities for the different facts. To these in order to render the history of the potatoe complete, an account of its original discovery, and the observations made on it by the first and early visitors to the shores of South America, should be obtained; and this research would probably lead to a detection of the circumstances attending its first introduction into Virginia, which is at present involved in obscurity.

ON THE GROWTH OF EARLY POTATOES.

BY E. H. DERBY.

Observing the produce of a few potatoe, which I transplanted the last year, to be very good, I was induced this season to try the experiment upon a somewhat larger scale. About the first of April I took some late white potatoe

after cutting them placed them in a hot bed, as close as they could lay, and covered them with earth. On the 21th of April, the plants being in fine order, some of them twelve inches high, I took them up and separating all the shoots but one from the parent potatoe, I made drills about three feet apart with a hoe, and filling the same with well digested manure; I transplanted as I should cabbage plants, the whole of the shoots about nine inches apart in the drills. On the 3d of May there was a very sharp frost, which injured the tops of the plants very considerably; they in a few days recovered and grew very rapidly, scarcely one of them failing. The rows were twice hoed. On the 30th of June I commenced using new potatoe, the size large, and very fine, equal to any taken up in October: finished digging them on the 10th of August; the land measured 90 by 52 links of the chain, on which stood one pear and plum tree, and produced at the rate of 293½ bushels per acre. The rows might have been much nearer, consequently the produce would have been greater. I could not perceive any difference in the yielding of the plants, between those which were separated, and the ones which adhered to the potatoe. Should I try the experiment again, I should take all the plants from the potatoe, and replant it as it appeared as fresh and sound as the day it was first put into the ground.

Vides, ut ultra stet nive candillum
Seraice! nec jam sustineat onus
Sylvæ laborantes.

Look! how white with snow stands mount Ida; and how the groves labor with the burden.

Remarkable weather.—The snow began to descend in broad, moist flakes, on Saturday morning, at about 8 o'clock, and continued its thick, fast and feathery fall, till about sun-set. About 12 o'clock it was heard to thunder, and again about 2. Notwithstanding a great part of the snow melted as it fell, it had covered the ground at night to the depth of at least four inches. It threw on the leaves and branches of the tall, slim poplars in our streets, so heavy a load as in a considerable degree to strip them of their honors; and in the afternoon there was scarcely a moment in which you could not hear the groan of some of those vegetable dandies, as they were divested, one after another, of their trim attire. The moral of the scene was impressive; and the day was calculated to inspire a sheltered and ruminating man, with a musing and quiet awe. The maples, the elms and chestnuts sustained the weight of the falling heavens without injury, for their branches had sprung from a good stock; their growth had been slow and solid, and their strength, in the hour of need did not fail. But the precocious and exotic poplars, brought from the warmer regions of the south, graceful, but frail, could not bear the brunt of our northern skies, and yielding the gay vesture to the storm, lost all when they lost their beauty.

'Thus may we find tongues in the trees;' and if our young men and maidens will listen to what those tongues teach, they will form for themselves characters that will sustain them in adversity and command respect in prosperity: the social affections, like singing birds, shall make nests in their branches, and the solid trunk of good principles shall sustain their honors.

[Troy Sentinel, Oct. 28]

For the following, together with some other valuable receipts and a "History of the Potatoe" we are indebted to "A Subscriber," who will please to accept our thanks for his valuable communications.

TO PRESERVE FRUIT WITHOUT SUGAR.

Reported to the Society of Arts, (England) by Thomas Saddlington.

Take gooseberry bottles, or the widest necked, common porter bottles; clean them; have the fruit picked but let it not be too ripe. Fill them as full as they will hold, to admit the cork to be put in; frequently shaking the fruit while filling. When done, fit the corks to each bottle, and sticking them in so lightly that they may be easily taken out when the fruit is scalded, which may be done either in a kettle, copper or sauce pan over the fire; first putting a coarse cloth at the bottom, to prevent the heat of the fire from cracking the bottles. Then fill the copper, or kettle with cold water sufficiently high for the bottles to be nearly up to the top in it. Put them in sideways to expel the air from the cavity under the bottom of the bottles. Take care that the bottles do not touch the bottom, or sides of the vessel which will endanger their bursting. Increase the heat, gradually 160° or 170° by a brewing thermometer, which will require about three fourths of an hour. If a thermometer cannot be had, the heat may be judged by the finger—the water being very hot, but not so as to scald it. If too hot add a little cold water, or slack the fire. When at this degree of heat, it may be kept so for half an hour longer, which will at all times be quite enough, as a longer time, or a greater heat will crack the fruit. During the time that bottles are increasing in heat, a tea-kettle full of water must be got ready to boil as soon as the fruit is done. If one fire only is used, the kettle containing the bottles must be half removed from the fire as soon as it attains the proper heat, so as to make room for boiling the water in the tea-kettle. As soon as the fruit is properly scalded, and the water boiling, take the bottles out of the water, one at a time and fill them within an inch of the cork, with the boiling water out of the tea-kettle. Cork them down immediately, doing it gently, but very tight, by squeezing the cork in, but you must not shake them by driving the cork, as that will endanger bursting the bottles, with the hot water. When corked, lay them on their sides, as this keeps the cork swelled, and prevents the air from escaping. Let them lie till cold, and then remove them to any convenient place of keeping, always laying them on the side till used. For the first month or two turn the bottles a little round, once or twice a week, to preserve the fermentation which will raise a scum on the fruit, from forming a crust, by which attention the fruit will be kept moist with the water and no mould will ever take place. It will be proper to turn the bottles a little round once or twice a month afterwards. The wide mouthed bottles will be best for convenience of getting fruit out for use. When used the first liquor poured off answers for pies, tarts, puddings, &c. in place of water as it is strongly impregnated with the virtues of the fruit. The last poured off, boiled up with sugar, makes a very rich and agreeable syrup.

Twenty four bottles were sent to the Society containing Apricots, Gooseberries, Currants,

Raspberries, Cherries, Plums, Orleans Plums, Egg-Plums, Damsons, Siberian Crabbs, and Green Gages. Apples and Pears may be done for shipping, &c. The Society voted a premium of five guineas for the communication. If heat greater—say 190 degrees is used, the fruit is reduced nearly to a pulp.

Ninety bottles of fruit thus preserved, cost the preserver, in London, £1, 9, 5½: in the summer; and in the winter, making allowance for breakage and other accidents, would sell at a profit of nearly 200 per cent.

NEW ENGLAND FARMER.

SATURDAY, NOVEMBER 8, 1823.

Extracts from a work lately published by WILLIAM COBBETT, entitled "*Cottage Economy*," with occasional remarks on some of the statements of the author.

[Continued from page 62.]

The following directions from Mr. Cobbett's work, above mentioned, relative to the choice of *Malt* and *Hops* may be of use.

"Malt varies very much in quality, indeed it must with the quality of the barley. When good, it is full of flour, and in biting a grain asunder, you find it bite easily, and see the *shell* thin and filled up well with flour. If it bite *hard* and *stely* the malt is bad. There is *pale* malt and *brown* malt; but the difference in the two arises merely from the different degrees of heat employed in their drying. The main thing to attend to is the *quantity of flour*. If the barley was bad, *thin* or *stely*, whether from unripeness or blight, or any other cause, it will not *malt* so well; that is to say, it will not send out its roots in due time, and a part of it will still be barley."

In order to ascertain whether the barley has been well malted, Mr. Cobbett directs to "take a handful of the *unground* malt, and put it into cold water. Mix it about with the water a little; that is let every grain be *wet* *all over*; and whatever part of them sink are not good. If you have your malt ground there is not that I know of, any means of detection.

"If the barley be all well malted there is still a variety in the quality of the malt; that is to say, a bushel of malt from fine, plump, heavy barley, will be better than the same quantity from thin and light barley. In this case, as in the case of wheat, the *weight* is the criterion of the quality. Only bear in mind that as a bushel of wheat, weighing *sixty-four* pounds, is better worth six shillings than a bushel weighing *fifty-two* is worth four shillings, so a bushel of malt weighing *forty-five* pounds is better worth *six* shillings, than a bushel weighing *thirty-five* is worth *five* shillings. In malt therefore as in every thing else, the word *cheap* is a deception, unless the quality be taken into view.

"There are two things to be observed in hops: the *power of preserving beer*, and that of giving it a *pleasant flavor*. Hops may be *strong*, and yet not *good*. They should be *bright*, have no *blossoms* or bits of *branches* amongst them. The hop is the *husk*, or *seed pod*, of the hop-vine, as the *cone* is that of the fir-tree; and the *seeds* themselves are deposited, like these of the fir, round a little soft stalk, enveloped by the several folds of this pod, or cone. If, in the gathering, leaves of the vine or bits of the branches, are mixed with the hops, these not only help to make up the *weight*, but they give a *bad taste* to the beer; and, indeed, if they are proper much, they spoil the beer. Great attention is, therefore, necessary in this respect. There are, too, many *sorts* of hops, varying in size, form, and quality, quite as much as *apples*. However, whenever they are in a state to be used in brewing, the marks of goodness are, an absence of *brown color*, (for that indicates *perished* hops) a color between *green* and *yellow*; a great quantity of the *yellow farina*; seeds not too large or hard; a clammy feel when rubbed between the fingers; and a lively pleasant smell. As to the age of hops, they retain for twenty years, probably, their *power of preserving beer*; but not of giving it a pleasant flavor. I have used them at *ten years old*, and should have no fear of using them at *twenty*. They lose none

of their *bitterness*; none of their power of preserving beer; but, they lose the other quality; and, there, in the making of fine ale or beer, new hops are to be preferred. As to the *quantity* of hops, it is clear, what has been said, that that must, in some degree depend upon their *quality*; but, supposing them to be good in quality, a pound of hops to a bushel of malt about the quantity. A good deal, however, depends upon the length of time the beer is intended to be kept, and upon the season of the year in which it is brewed. Beer intended to be kept a long while should have full pound, also brewed in warmer weather, than for present use. Half the quantity may be done, opposite state of circumstances.

"The *Water* should be soft by all means. The brooks, or rivers, is best. That of a *pond*, fed by rivulet, or spring, will do very well. *Rain-Water* just fallen, may do; but stale rain-water, or stagnant pond-water, makes the beer *flat* and difficult to keep, and hard water, from wells, is very bad: it does not get the sweetness out of the malt nor the bitterness of the hops, like soft water; and the worst of it is, it ferments well, which is a certain proof of its unfitness for the purpose."

A Superlative Turnip.—Ebenezer Hobbs, of Weston, Mass. has raised this year, a turnip weighing *eleven pounds* and a half without the top. It is somewhat superior to the Worcester and Leicester turnips, and deserves of course a higher station among the vegetable prodigies of this prolific season.

FOREIGN.

Eylate arrivals, Liverpool papers have been received to the 27th September.

The Citadel and town of Pampeluna have surrendered to the French, and the garrison sent into France. A disease had broken out among the French troops at St. Sebastian. Marshall Lauriston had marched 12,000 men to reinforce Menecy's corps in Lower Catalonia. The prisoners taken at the Trocadero amount to 1100 men, who have been sent to Xeres. A prisoner from Madrid of Sept. 17th, says in a postscript the corps of Riego had been completely routed by French. Preparations continued to be made for the siege of Cadiz. A letter from Valencia dated the 9th of September, states that a victory had been obtained by Milans over the French army, consisting of 10,000 men, commanded by Menecy in person. The engagement took place on the 25th of August, at Antan, some leagues N.E. of Tarragona. It was maintained with extraordinary obstinacy on both sides, and determined by a decisive attack with the bayonet along the whole line on the part of the Spanish army, who broke the enemy and drove them off the field. The cavalry of Milans pursuing them for several miles in various directions. Milans makes the French loss amount to near 17,000 men, of whom 1700 were officers; that of the Spaniards to something more than 6000. An article, dated Madrid, Sept. 9th, says, "Official advices from St. Mary's announce that the Dep. Don Miguel Alava, arrived there the 4th inst. on flag of truce, bearing a letter from the king of Spain to the Duke D'Angoulême, and it was asserted that the Duke will agree to no other condition but the liberation of the king." Cadiz letters assert that capture of the Trocadero had entirely changed the face of affairs there; and that there were conflicts between the militia and troops of the line.

The Boston Centinel of the 5th inst. asserts that negotiation for a cessation of hostilities appeared to be certainly in train at Cadiz and vicinity. Informal of it had been dispatched by the British Minister A'Court from Gibraltar. It had received the immediate attention of the British Ministry, and the answer thereto had been despatched by Mr. Canning, a King's messenger, and an officer; and a sloop of war had been ordered to convey the answer of the British Court with all speed to Spain. The Courier of the 13th says, "the news is of great moment." French Ministerial papers asserted positively that the Duke would not agree to any other basis than the restoration of the King to liberty, and the surrender of Cadiz to the royal Spaniards. This basis established it is said the guarantee of England of other conditions would be admitted.

all later from Europe.—The ship *Montano*, arrived from New-York from Havre, has brought Paris papers to 24th of September. A *Moniteur* of the 23d contains an official letter announcing the capture of Gen. Oudinot, three leagues from Carolina. The French flotilla, based at the entrance of the River St. Peter, near St. Mary, in the month of August, took, sunk or burnt 56 ships of various sizes, most of them laden with flour, other provisions for Cadix.

Transfer of Cadix.—The brig *Mary* and *Eliza*, Capt. J. G. Gibraltair on the 4th ult., arrived at this port on the 6th inst. and informs that the city of Cadix surrendered to the French forces on the 29th of September, and that the King and Royal Family, on the 1st day, passed over to the French Head Quarters at St. Mary.

DOMESTIC.

New-York Cattle Show and Fair, is highly spoken of. We have not yet received the details of this exhibition. The premiums, we learn were paid in silver and books as well as in money, and many ladies led them in person together with the acclamations of the spectators. The first premium for black broad cloth, which brought \$10, 25 per cent and the second \$9, 75. A Gipsy Leghorn Hens, by Miss Harrison was bought by Mr. John Leontine, \$100; and another by Miss Babcock brought \$100. The Hon. W. P. Van Ness presided at the dinner the guests were the Hon. De Witt Clinton, Hon. Minister to Chili, Col. Gibbs, &c.

Hampshire Cattle Show.—The annual Cattle Show, the Hamp-Lire, Franklin, and Hamden Agricultural Society, was held at Northampton, on the 22d and 23d of October. "The exhibition of Household Manufactures was far superior to that of any preceding year in number, variety and excellence of the articles." "The stock was decidedly inferior to the exhibition of former years." The Swine were good and of considerable improvement. The fine woolled were not numerous, but some of them very superior.

The Address of Mr. Bates," says the Hampshire Farmer, "we shall only express the sentiments of the audience by expressing our own admiration. It was a practical address—appropriate to the occasion, and the truth of his remarks and advice were well set off by taste and fancy of the writer, and his graceful and impressive delivery. We understand the address published." The performances of Mr. Lucas, a choir of singers, on the evening of the first day of the Cattle Show are spoken of in terms of approbation. We propose to give further notice of this exhibition when we have received the detailed and official reports which are expected.

Town of Eaton against the world, for corn and wheat.—At the late Show and Fair, says the *Northampton* (N. Y.) Observer, Benjamin Bartlett produced "satisfactory proof," that he raised one hundred and seventy-four bushels of corn upon an acre of land, and also that he raised three hundred and fifty half bushels of Potatoes, upon one half acre of land, for which he received the first premiums. To the sons of Johnnycake, and to the sons of swate Ireland, this must be cheering news. Those who are united with the fertility of our soil may be disposed to doubt the above. But every doubt will be removed by referring to Mr. Bartlett, who is an experienced agriculturist, and who will explain the process of mode of culture by which these enormous crops were produced.—*American Mercury*.

Beet.—There was lately exhibited in Bridgewater, Jersey, a beet raised by Samuel Seeley, of that place, which weighed nineteen pounds.—The species called *beta vulgaris*, containing choline matter than the Mangel Wurtzel, and heavier in proportion to its size. Larger beets are raised in New England, and there was one raised in Ohio, (of which notice was taken in our 1st No. 44,) which we are told weighed thirty pounds!—A very prodigious beet was from the seed of *Burr's Sugar Beet*.

Mr. Manmoth Turnip.—Mr. John Sargent of this year raised an English Turnip, which

weighed without the top, 8 lbs. 11 oz. and measures 22 inches in circumference, and 4-3-4 inches in thickness, although it has been some time exposed in a situation in which it would be likely to shrink.

It was raised in a corn-field in a part no richer than the common soil of the field, and had no particular care bestowed in its cultivation.—*Com. for the Mass. Spy*.

Singular Phenomenon.—On the 11th ult. about twelve miles from Madison, in Jefferson county, on the road to Verona, two explosions took place in quick succession, in the bottom of a branch near the house of Mr. Badgley, which cracked the rock for a considerable length, and threw up a quantity of mineral, intermingled with white spar. It is yet unknown what kind of metal it is. The report was so loud that it was heard at the distance of four miles, and those living in the immediate vicinity were very much alarmed. This is a singular occurrence, and such an one as we do not recollect to have heard of before, unless accompanied by an earthquake. One of the editors has been on the ground since the explosion, and examined the creek and the mineral which was thrown up by the explosion. Some of the rocks that were broken appear to be very large sheets, and the effect produced upon them much greater in extent than would be produced by a blast from powder.—*Western (Ohio) Cent.*

Distressing Occurrence.—On the 11th of October the house of Mr. Augustus Todd of Bertie, County, N. C. was destroyed by fire and two of his children were burnt to death; the house having taken fire, by accident while the father and mother were absent at a neighbour's house. A negro man, who was at work, at some distance from the house, seeing the fire ran to save the house but arrived too late. The unfortunate father had three children, two of whom were in the yard at play when the fire broke out; but the eldest son on discovering the fire ran to the rescue of the child from the danger, and fell a victim to the flames.

Duelling.—The Grand Jury of Charleston, S. C. have presented duelling to the Legislature as one of the greatest crimes against the peace and welfare of society, and recommended that provision be made to disqualify the principals and seconds engaged in duels from holding places of honor and profit.

A Warning to Quacks.—One Dr. Miller, in the interior of New-York, has had Judgment rendered against him for \$600 for mal-practice in undertaking to set the arm of a young woman, which had been dislocated at the elbow, and which had been rendered entirely useless by his negligence or ignorance.

A writer in the National Intelligencer, with the signature of "A Farmer," laments the destruction of timber in the best cultivated parts of the United States, and advises the planting forest trees, extensively, for fuel and lumber.

House of Industry.—The Agricultural experiments made at this Institution have succeeded beyond expectation. A lot from which a fine crop of hay was cut in July, has since produced several hundred bushels of excellent turnips.—We have seen some of them, which measured twenty two inches in circumference, fair, round, smooth, and finely flavored.—*Boston Centinel*.

Manmoth Calves.—A yearling calf, was exhibited at the Saratoga Cattle Show, which weighed 1325 lbs.; and a calf ten months old, which weighed 672 lbs. both raised by Mr. Gilbert Waring.

Early Snow.—On the 25th ult. snow fell in Cherry Valley, N. Y. to the depth of 12 inches or more. At Lansingburgh, in the same day, a violent snow storm accompanied with thunder and lightning, was experienced which left the snow a foot deep.

A very fine Grass Hat.—Miss Betsey Belcher, of Albany, at the late Agricultural Fair in that city, exhibited a grass hat, which was purchased by the President of the Society at auction at \$50.

Capt. Joseph Edwards, an enterprising and industrious mechanic, of this town, lately removed the Asylum House in Carpenter-street, with the chimneys, furniture, and fixtures, over thirty feet, by means of a slide.

The family were within, attending to their concerns, while the house was moving. We understand that neither the walls, nor the brick work in the chimneys, received the slightest injury by the process of removal. [*Salem Observer*.]

TO CORRESPONDENTS.—We have received several communications from respected correspondents, which shall meet with all possible attention; but some time must be allowed us to comply with their requests and intimations. We have a plan for an Ice House in the hands of the Engraver, which we hope to insert in our next. For the hint we are indebted to a correspondent who takes the letter "R." for his signature, and whose valuable communication respecting the best mode of clearing land from *pine stumps*, &c. shall soon be published.

The request of the gentlemen who wishes for a list of the most "approved agricultural works" shall be complied with as soon as we can command time sufficient to make some inquiries connected with the subject. We wish not only to give the required list, but to state where the books may be obtained; and this information we hope to furnish; but personal interviews with some of our friends who have agricultural books for sale will be necessary in order to make the article as complete as we hope to be able to render it.

From the Providence Journal.

AGRICULTURAL ODE FOR THE YEAR 1823.

Awake your joyful minstrelsy:
But not the clamorous note of war,
To tell the deeds of chivalry,
For Independence done.
Nor yet recount, how soared the star
Of Freedom, o'er the ocean wave,
When, late, in combat met the brave,
And victory was won.

The warrior's trophy, stained and torn,
No pleasure can on us bestow;
'Tis purchased with the widow's moan,
The orphan's sigh of woe.

Awake the note of mirth and glee,
For bloodless triumphs, all our own;
Fit subject, these, for minstrelsy,
And pleasure's genial glow.

In hope we ploughed the stubborn soil:
In confidence the seed was sown:
The harvest blessed our patient toil,
And plenty crowns the year.
The Artists' trophies, too, are won:
The Loom its well wrought web unfolds,
To shield us from the scorching colds
Of winter's blasts severe.

Our commerce sweeps, with swelling sails,
Fearless, o'er ocean's wide domain,
Borne onward by his favoring gales;
Nor tempts his storms in vain.
Returning from far distant shores,
With teeming wealth her honest gain,
Upon our happy lands she pours
The treasures of the Main.

These triumphs, Industry, are thine;
And long may Peace, protract thy reign:
Such blessings may we ne'er resign,
A name in war to gain.
The warrior's meed is but a name:
Glory's an empty phantasy:
Her brightest hallow is a flame
Of splendid misery.

MISCELLANY.

Iron Mountain in Missouri.—This place is in Washington County in this State, and is the most extraordinary store that has yet been discovered in any country. It would not probably be transcending the limits of truth to say, that it would supply the world with this useful mineral for a long period of time. In appearance it bears a strong resemblance to native iron, and would yield, on fusion, 80 or perhaps 90 per cent.

There are other places that have been denominated *iron mountains*, such as that of Traberg in Poland, and two, the names of which we do not recollect that have been discovered in Lapland; but none of these can be compared with the mountains of Missouri, neither in point of magnitude, nor in quality of ore.

It is a matter of astonishment that no foundry has yet been established convenient to this place; in its neighborhood are many valuable mills, and there is evidently no want of water power for the application of machinery, even of the largest construction. As there are few individuals who could command the capital necessary

to be employed in this business, it would perhaps, require a company to carry into effectual execution, an enterprise of so much importance, and which could not fail in being amply productive. Of the success that would attend it there cannot exist a doubt, and it is thought, by many intelligent persons, that iron, castings, &c. might be exported advantageously even to places where they are now manufactured.

The peculiar quality of the ore of which this section of country is the rich depository, is also worthy of attention. At a *Bloomery*, erected by Messrs. Perry and Ruggles, iron is produced of a quality greatly superior to any that can be imported, and is preferred by smiths, because it is worked with greater facility, and is found to possess, in a very high degree, the properties of steel. Axes, plough-irons, and other implements of husbandry, made of this iron, without any addition of steel, is found nearly equal to those formed in the ordinary way.

The *iron mountain* is frequently visited by the curious traveller, and by those who have contemplated drawing on its vast store of wealth; and at length it is stated, a foundry and other works, calculated to bring into operation the mineral resources of this district, are about to be erected. We do not vouch for the truth of this statement, but a better prospect for the investment of capital is but seldom presented, and there can be no doubt, that, if not immediately it will soon, be embraced.—*St. Louis Inquirer.*

Lieut. Kotzebue has discovered in the western part of the gulf to the north of Beering's Straights a mountain covered with verdure (moss and grass) composed entirely of solid ice. On arriving at a place where the shore rises perpendicularly from the sea to the height of 1000 feet, and continues afterward to extend with a gradual inclination, they observed masses of the purest ice 100 feet high, preserved under the above vegetable carpet.—The portion exposed to the sun was melting, and sending much water into the sea. An undoubted proof of the ice being primitive (i. e. not formed by any causes now in action) was afforded by the great number of bones and teeth of the mammoth which make their appearance when it is melted. The soil of these mountains which, to a certain height, are covered with abundant herbage, is only half a foot thick; it is composed of a mixture of clay, earth, sand, and mould: the ice melts gradually beneath it, the carpet falls downward, and continues to thrive.—The latitude is 60 deg. 15 min. 36 sec. N.

Belzoni, the Traveller.—This enterprising traveller is now on an exploratory journey in northern Africa. A letter has been received from him, dated Fez. He had had the honor of being presented to the Emperor of Morocco, and obtained his Majesty's permission to join the caravan, which would set out for Timbucto in one month after the date of the letter. "If nothing," writes this enterprising man, if "nothing should happen, and if promises are kept, I shall from this place cross the mountains of Atlas to Tallet, where we shall join other parties from various quarters, and from thence, with the help of God, we shall enter the Great Sabara to Timbucto. Should I succeed in my attempt, I shall add another votive tablet, to the temple of Fortune; and if, on the

contrary, my project should fail, one more will be added to the many others which I fallen into the river of oblivion." We understand that his design is first to reach Timbucto and from thence continue his route through heart of Africa to Sennar. He will then, through Nubia, arrive once more in the far Egypt, the scene of his memorable discovery.

A Poet's Disinterestedness.—Mr. Pope nattered any body for his money in the course of his writings. Alderman Barber had a great inclination to have a stroke in his commend: inserted in some part of Mr. Pope's works. did not want money, and he wanted fame. would probably have given four or five thousand pounds to have been gratified in this; and gave Mr. Pope to understand that Mr. Pope would not comply with such a request; and when the Alderman died he left only a legacy of a hundred pounds, which he have been some thousands if he had oblige him with only a couplet.—*Spence's Anecdotes.*

Enough is as good as Superabundance.—V. Mr. Pope's nephew that had been used to sea, refused a very handsome settlement was offered him in the West Indies, and that fifty pounds a year was all he wanted would make him happy. Mr. Pope, instead using any arguments to persuade him not to use so advantageous a proposal, immediately to settle the yearly sum upon him which he said would make him happy.—*Ibid.*

The Tendency of Writing.—No writing good that does not tend to benefit mankind some way or other. Mr. Waller has said "he wished every thing of his burnt that did not impress some moral."—*Ibid.*

Poetry well paid for, and yet a good barge the Purchaser.—A little after Dr. Young published his Universal Passion, the Duke of Wharton made him a present of 2000l. for. When a friend of the Duke's, who was sued at the largeness of the present, cried "What! two thousand pounds for a poem? Duke smiled, and said it was the best he ever made in his life, for it was fairly worth four thousand."—*Ibid.*

Contentment.—There are two sorts of contentment; one is connected with exertion other with habits of indolence: the first virtue, the second a vice. You may sometimes see a man in sound health submitting day after day, to evils which a few hours labor would remedy; and you are provoked to hear say; "It will do well enough for me. I do it for my father before me? I can make shift with things for my time—any how contented." No man ought to be contented with any evils which he can remedy by his industry and exertion.—*Miss Edgeworth.*

TERMS OF THE FARMER.

Published every Saturday, at THREE Dollars per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at discretion of the publisher,) until arrearages are

NEW ENGLAND FARMER.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

Vol. II.

BOSTON, SATURDAY, NOVEMBER 15, 1823.

No. 16.

Farmer's and Gardener's Remembrancer.

[BY THE EDITOR.]

REMARKS ON PLOUGHING.

[Concluded from page 114.]

disputes have arisen among farmers in this country and in Europe relative to the best manner of laying the furrow slice. Some contend turning the furrow slice completely over, laying it quite flat; but others allege that the most advantageous to place each slice in a manner that its outer edge may extend little over the inner edge of the furrow which is drawn next before it. "In several districts of England it is usual to lay the furrow slice flat, and this is particularly the case where there are no ridges; but in Northumberland, and in Scotland, a contrary system is adopted. Founded on this idea, that as two of the principal objects in ploughing are, to expose as much as possible to the influence of the atmosphere, and to lay the land, so that the barrows, in the most effectual manner, raise mould over the seed; these objects are most effectually accomplished, by ploughing land of every ripeness, with a furrow slice about seven inches deep, and which, if about ten inches and if broad, raises the furrow slice, with a shoulder, forming the angle 45, the point ought to be referred to, when determining between the merits of different specimens of ploughing. For that purpose, the depth of furrow, should, in general, bear a due proportion to the breadth, that is, about two thirds, six inches deep is to nine broad. This is in general, if not the universal opinion of the farmers.* The angle 45 is strongly recommended in Bayley's Essay on the Construction of the Plough, in his Durham Report and Brown's Treatise on Rural Affairs. In the northern counties of England, however, they usually prefer to turn the furrow quite flat, horizontal; and allege as a reason for that, that the weeds, grass, &c. ploughed underneath cannot well be smothered or withered, unless the roots are turned completely bottom up, and the turf covered so closely as to have communication with the atmosphere. "Ridged land is frequently cultivated by an implement called the *Binot*, which is highly esteemed. By this instrument the land is not turned over, as by the plough, and the weeds lie flat; but the soil is elevated and pressed into ridges, and thus is better exposed to the beneficial influence of the winter frosts, and becomes sooner dry in spring than when it is turned over perfectly flat. When the furrow slices are set up edgewise by a plough, they become small thin ridges, are more easily dried by frost, and are in a situation to attract the fertilizing influences of the atmosphere more than when they are turned over so in a horizontal position. Perhaps this mode of ploughing land may be advantageous in hard soils, where several ploughings are necessary to prepare for the reception of the seed. If land of this description is broken up

in the fall or summer preceding the sowing or planting of the seed, and cross ploughing in the spring is made use of, preparatory to putting in the seed, we are inclined to think that the "feather edged ploughing" as it is sometimes called, (in which the furrow slices are not laid so flat as to exclude the air from between, and from the lower part of the furrow slices) is to be preferred. "Ploughing previous to winter setting in is of great use to clays, or stiff lands, exposing the surface to the frost, which mellows and reduces it in a manner infinitely superior to what could be accomplished by all the operations of man."* If, then, exposing the surface of stiff soils to the frost is of great advantage, the more surface there is exposed the greater the advantage; and if the furrow slices are set partly or entirely on their edges there will be, as before intimated, more surface exposed than there would be if they were laid perfectly flat. And if they were turned in such a manner as to form an angle of 45 degrees, the outer edge of one furrow resting on the inner edge of that which immediately preceded it, there would be but little chance for the weeds or grass to grow up between the furrows, which may be the case, when the slices are set perpendicularly, or nearly so, on their edges. There will likewise always be a cavity under the edges of the furrow slices, containing stagnant, and sometimes putrescent air, which will enrich the soil. Moreover if ridge-ploughing is at all advantageous, we cannot see why a mode of ploughing, which makes a ridge of every furrow slice, or at most a ridge by turning the edge of one furrow slice on the edge of its immediate predecessor should not be likewise of advantage. Besides, by these modes of ploughing you form a covered or open drain or hollow place, between the furrows, which by carrying off superfluous water will render the soil fit for tillage earlier in the spring than would be possible if every furrow slice was laid flat as it was turned upside down. The harrow will also more readily take hold of a soil, where the furrow slices form little ridges or protuberances, and thus a proper mould will be procured for the covering the seeds, or earthing up plants in a growing crop. And if there is danger of the lands lying too loose and hollow, repeated harrowing, and rolling it with a heavy roller after sowing will furnish a remedy.

Dry sandy soils, such as ought not to be ploughed in ridges should be turned over completely, and be laid and kept level as possible. Such soils, if rendered loose, and laid light by cultivation will be robbed of their fertilizing particles as well by rain as by sunshine. In other words they are liable to suffer by washing, by scorching, and by too much draining. They do not need to be made any lighter, by "feather edged ploughing" or setting the furrow slices edgewise, being too light under ordinary cultivation. It is therefore "a great advantage to such soils to fold sheep, or to consume the crops of turnips upon the ground where they are raised.

* See *Husbandry of Scotland*, vol. i. p. 229, and vol. xi. Appendix, p. 26.

These practices greatly contribute to the improvement of such soils, not only by the dung and urine thus deposited, but by the *consolidation and firmness of texture* which the treading of sheep occasions."*

On the whole, although it would not be possible to give general rules not liable to many exceptions, on the shape and position of the furrow slice, which should be cut and disposed of according to the views of the cultivator, the nature of the ground, the proposed crop, &c. we are inclined to believe that Sir John Sinclair's maxim will apply to most of our New-England uplands. That eminent agriculturist says that "the point which ought to be referred to, when determining between the merits of different specimens of ploughing is the angle of 45 degrees." That is, other things being equal, the nearer the furrow slice comes to forming an angle of 45 degrees with the horizon, the more perfect the specimen of ploughing. But another maxim of the same writer is equally worthy of attention. "Dry soils being deficient in moisture ought to be tilled flat, as any sort of drainings which the furrows might afford would be prejudicial rather than advantageous. In Kent, dry land is left as level as if it were dug with a spade. The moisture is thus equally diffused and retained under the surface of the earth."

* *Code of Agriculture.*

MAKING CIDER.

Although we have heretofore, with the aid of our correspondents, given pretty copious dissertations on the subject of manufacturing cider, we confess that the following article, copied from the Portsmouth Journal of the 11th ult. has furnished a new idea on this subject which we believe may be useful.

"Cider.—Your casks must be clean and in every respect well prepared to receive the liquor. On the evening of the day you make your cider, place it in your cellar. Take one quarter of a pound of isinglass, (made of hake sounds) and put it in two quarts of cider—place it by the fire, and let it simmer and dissolve. Then put it into your hoghead of cider, well secured from air, except a small vent hole, and your cider will be perfectly clear and remain sweet and good for years. For a barrel, let there be used two ounces."

The following remarks in Sir Humphrey Davy's Lectures on Agricultural Chemistry will explain the reason on which this process may be founded.

"Fabroni has shewn that the *gluten* in must is essential to fermentation; and that chemist has made saccharine matter ferment by adding to its solution in water, common vegetable *gluten* and tartaric acid." The acid is supplied by the fruit, but the gluten may be obtained perhaps to most advantage from the isinglass. Thomas Cooper, M. D. of New Jersey has recommended the use of *calves feet jelly* as a substitute for isinglass. If, however, gluten is used either in the shape of isinglass or calves feet jelly, you should think it might be best to omit the ar-

cation of the alcohol as recommended in page 33, vol. ii. of the New England Farmer; or at least not to add the alcohol or spirit of any kind, till after the cider had done working, or the vinous fermentation was completed. Gluten is not soluble in alcohol, and we apprehend that its addition in any considerable quantity to must or new cider which holds gluten in solution would cause the latter to fall down, or be precipitated as chemists express it, before it had produced its desired effect in promoting the vinous fermentation. Of this, however, we are not certain, (as the alcohol would bear but a small proportion to the quantity of the liquid) and, perhaps experiments alone can decide the question.

AN ADDRESS

*Delivered before the Gracian (N. H.) Agricultural Society, at their Annual Meeting, October, 1822.
By Thomas Whipple, Jr. Esq.*

Mr. President,

Gentlemen of the Society, and Fellow Citizens,

In my attempt to address you on this occasion, I feel no inconsiderable degree of diffidence and want of confidence in myself, to do justice to a subject which is in itself highly important to the well being of our community; but every member of the community ought to exert himself to aid the whole, and however defective may be his labors, yet he ought to submit them, subject to the better judgment of those who may have more time or leisure to contribute to the fund of general knowledge.

Agriculture in its general sense, comprehends a knowledge of the nature of the soils, with which we meet, on and near the surface of the earth; the methods of correcting those which are unfavorable to the production of useful vegetables; the improvement of such as are deteriorated by our cropping; such implements as are fittest for facilitating the operations of the husbandman; the means and powers best adapted to such purposes; the cattle and live stock most profitable to man whether for labor or more immediate use as food; the grasses, grains, roots and pulse most beneficial to him, and the minor subjects connected with this important science. The objects of agriculture, must then be, of primary import to man, and his condition will be found more or less meliorated, according to his greater or less progress in the science of husbandry.

One of the greatest concerns, of every wise people, and enlightened government, must then be, the improvement and perfection of the husbandry of the country, which they inhabit, or over which it may exercise control.

Of all the arts, (says the learned Vattel) tillage or agriculture is doubtless the most useful and necessary, as being the source, whence the nation derives its subsistence. The cultivation of the soil, causes it to produce an infinite increase; it forms the surest resource and the most solid fund of riches and commerce, for a nation that enjoys a happy climate. This object then deserves the utmost attention of the government and people. The sovereign ought to neglect no means of rendering the land under his jurisdiction as well cultivated as possible.

It would be useless to multiply arguments and authorities, to satisfy ourselves, of what has been admitted by the reflecting of almost all countries and ages of the world.

If improvement in agricultural science, is important and necessary to the well being and happiness of other nations, it is peculiarly interesting to the people of the United States.

The American farmer pursues his occupation under circumstances of peculiar felicity. His tenures being allodial or fee simple, he is enabled to enjoy the utmost avails of his labor, to provide for his ease and comfort, and to transmit to his posterity, free from any prejudicial restraints, whatever of his property may remain at his decease.

Nor are the agriculturalists of the United States, (more especially those of New-England) considered as a degraded class of society; but the manners and habits of thinking in the United States, have remedied the abuse, of which Vattel so justly complains, as injurious to agriculture, at the period in which he wrote. "Another abuse (says he) injurious to agriculture, is the contempt cast upon the husbandman. The trades-man in cities, even the most servile mechanics, the idle citizen, consider him that cultivates the earth, with a disdainful eye; they humble and discourage him. They dare despise a profession that feeds the human race, the natural employment of man. A little insignificant haberdasher, a tailor, places far beneath him, the beloved employment of the first consuls and dictators of Rome."

If at the present day, a vestige of feeling remains, in any class of community, were it to be expressed, he who should utter the sentiment, would rather be considered as a suitable inmate for a lunatic asylum, than fit for rational society.

An art so necessary, useful and beneficial, as is that of agriculture, it should seem, that all would wish and conspire to improve. But how shall the husbandmen, effect their desirable object? It may be replied, that in this, as in every other department of knowledge, system will be found to be, an indispensable auxiliary. ARISTOTEL'S method is the best, was the saying of one of the seven wise men of Greece; and it will be found as applicable to any attempts, to improve agricultural knowledge, as, to all the other arts and sciences. So long as the farmer shall be confined to his own limited experience, and possess himself of no other materials for knowledge in his art, than the detached and scattered facts, which he may casually derive, from the experience of his more immediate neighbors, so long, he will make but little progress, in improving himself in the art of husbandry. Measures should be adopted by the agricultural community, to embody the experience and improvements, of other nations, inhabiting countries similar to our own, in soil and climate; to collect and preserve the valuable facts, observations and discoveries in agricultural knowledge, which are scattered over the surface of our extensive territory, and which are to be found in documents not accessible to the great mass of our farmers, to acquire correct topographical knowledge of the counties within our own state; the state of property therein, farm buildings, mode of occupation, implements, fences, arable land, grass, orchards, plantations, draining and other improvements, live stock, rural economy, the defects which exist in the present system of management, and the most probable and least expensive means of remedying them.

Our soils should receive particular attention. It must occur to every one, that different varieties of soils, must require different treatment and culture.

The division of soils into clayey, loam, calcareous, sandy, gravelly, peaty or mossy; vegetable earthy soils, as they are found in nature, lays the foundation for improving each, very different principles.

By different combinations of these substances all the intermediate kinds of soils are formed and upon a proper mixture of them, in certain proportions, depends the success of the farm industry. But if the cultivator, understands the nature and properties of the soil subjected to his culture, how will he be able to make the admixtures, which may improve it?

If calcareous, argillaceous or silicious matter, predominate in any given soil, so as to render vegetation feeble, an addition of great quantities of either of these kinds of earth would increase the cause of unproductiveness. A more intimate and scientific knowledge of the nature of our soils, must then be necessary, to successful cultivation of them.

I am aware, that long settled habits of thinking, on agricultural subjects, will lead many to the conclusion, that common observation will supply every defect, and remedy every error in the culture of our soils. But, does not common observation evince, that no inconsiderable portion of our farmers are rather declining in their circumstances, and becoming less and less able to produce sufficient supplies of agricultural products, to afford ease and plenty, in the domestic circle? Hence, frequent emigration in quest of a better country: or what is worse many are discouraged by bad crops, cease to exert, and sit down in despair, consoling themselves with the fallacious saying, that "the hired laborer, fares no better than the idler." Should we do well to substitute the saying of an ancient writer on agriculture, "it is not the quantity of labor, but the skillful application of which produces plenty?"

There has heretofore been less necessity for a scientific investigation of the constituent principles of our soils, because, when our lands were first reduced from a state of nature, they were covered with the rich vegetable matter produced by the successive layers of leaves; other vegetable matter, annually decomposed upon their surface; but successive cropping, exhausted this rich source of supply to the farmer, and brought him in contact with the primitive ingredients of the soil which he is to cultivate, and from which, he must not only derive his food, but his wealth.

This impoverished state of our soils is a great source of disquietude, and the promoter of the spirit of emigration. But, does it become an enlightened people, like the hordes of the north of Europe, first to exhaust their means of subsistence, and then migrate in quest of other provinces, that they may devour also, the productions of the earth, destined by the beneficent Creator for the support of other families and mankind?

It is important (says Seybert in his statistics) to consider what will be the effects of migrations on the agriculture of the Atlantic States. Many valuable farms originally productive have been abandoned after they were exhausted and made barren from constant culti-

on and no application of the means to restore their lost fertility. If migration be continued under these circumstances some districts will reappear exhibit all the features and poverty of a desert, and extensive tracts of valuable land will be a waste to the injury of our agriculture, manufactures and commerce.

If our country is not to be left waste, and incapable of sustaining a rapidly increasing population, means must be adopted to restore our lands to their original productiveness.

I have made these general observations upon the nature and objects of agriculture, its importance to mankind, its tendency to improve the condition of society, the propriety and necessity of placing it in the most respectable and honorable place among the arts, of aiding it by means of scientific knowledge, and the fallacy of some of the prevailing ideas respecting it. I might estimate the importance of zealous and systematic efforts to improve it.

Although individual exertions may do much, the improvement of agricultural knowledge, neither individual exertions, however well aided, or well directed, have been found sufficient, to advance the interests of husbandry with any effect.

A cursory view, of the agricultural history of Great Britain, will convince us of this fact. We are induced to wonder, that among a people, and under a government, where the arts and sciences have been patronized with a munificence liberality, creditable to the government, frequently oppressive to the people, no regular system, for the improvement of the agriculture of the country, should have been adopted until as late as 1793.

According to their best historians, the agriculture was at a low ebb until the 14th century, at which time, it began to be practised in the middle and northern parts of England. It seems however, not to have been cultivated in science, until the latter end of the 16th century; at which time, Fitz Herbert published his first work, entitled "the book of husbandry" from this period, to the time of the Commonwealth under Cromwell, small advances were made; when Sir Hugh Platt, discovered the method to use a variety of manures, for fertilizing and recovery of exhausted soils. At the time of the restoration, agriculture appeared to have been much neglected, until Evelyn and Tull, excited the attention of the nation to its importance and utility. After their death up to the year 1790, many valuable improvements, were made in the practice, and several eminent writers, rendered important services, by enlightening the minds of their countrymen and inducing emulation among them. About the year 1790, Sir John Sinclair, who distinguished for his genuine patriotic philanthropy, conceived the idea of a national board of agriculture; and in the year 1793, after the efforts of its utility were removed, and the delay attending all novel attempts at improvements were overcome, the charter of this noble institution was granted. To this society Dr. Gregory, we are indebted for 80 volumes of the most useful agricultural knowledge. A work comprising so many important objects of the science of agriculture, cannot fail of producing national benefits, greater perhaps than have been derived from any other political institution of modern times. By pursuing such a

plan for a few years, and publishing to the world such communications, under some systematic arrangement, we may expect, that agriculture will become the best understood and the most accessible of any art, in the whole circle of human acquirement. We have in this short epitome of the agricultural history of England much to excite surprise, much to avoid, and much to imitate.

We are surprised, that among a people whose words antedate the christian era, who so early that epoch, had intercourse with the Romans, the most civilized and most advanced in arts and sciences of any people of the earth; who passed through many revolutions in the state of their society, and had intercourse with so many neighboring nations, who excelled in the spirit of chivalry and retained an ardent desire for freedom, and who frequently suffered extreme distress from famine, and almost continual difficulties from short crops, should have neglected their agricultural interests, until as late as the 14th century, and after that period should have left them to be advanced by individual exertion alone, until the year 1792.

We ought to avoid the apathy which seems to have prevailed among this people respecting agriculture; but we ought to admire and imitate the zeal with which when once the powerful machinery of the national board of agriculture was put in motion, they seconded every revolution and accelerated its velocity, until several million acres of land which had before been waste and considered unproductive were reduced to a state of high improvement and almost every field in the kingdom grew green and luxuriant under its influence, as if new and fertilizing dews had been sent down from heaven to bless and cheer the efforts of the husbandman. The history of our own agriculture will equally convince us that individual exertion is incapable of producing that improvement in agricultural knowledge which its importance demands.

It will be unnecessary however to enter into details where a subject is so well known and time will permit the mention of a few facts only. Prior to the introduction of systematic efforts, by means of agricultural societies, to improve our husbandry, the whole agricultural products of the United States, were estimated at only about \$200,000,000. In 1817, a short time after the system for improvement was introduced and before it had time to extend and perfect itself and to produce the beneficial results which may hereafter be expected from it if persevered in, our agricultural products, were estimated at \$162,534,000. He who has travelled in those sections of our country where these institutions have overcome the difficulties incident to their first formation and are now in the full tide of successful experiment, will ask no other or better evidence of the superiority of united, over individual exertions for the improvement of the agriculture of a people—his conviction is involuntary and perfect.

The several agricultural societies within this state have been recently united by the intervention of a board of agriculture and the foundation laid for a systematic plan of improvement. By the agency of this board, the farmer will be enabled to receive a compend of useful information respecting the art of husbandry, and will be relieved from the labor necessarily required to make him acquainted with the more

voluminous and less condensed works on the subject of agriculture.

The County Societies will annually contribute to increase the fund of knowledge and hasten the work and excite the spirit of improvement and emulation.

We have to lament that the difficulties and obstacles incident to the formation and successful operations of such institutions have not been entirely overcome. It was to have been expected that upon the first advances of the government in the grant of the charter and a fund for premiums to excite emulation, every respectable farmer within the county would have hailed the event with joy and readily tendered his exertions to accelerate the progress of agricultural improvement.

With a population of 8653 engaged in agriculture according to the last census, we regret to find only the number of 139 enrolled as members of the Grafton Agricultural Society of which number 25 are professional men and a number of others engaged principally in trade. Doubt seems to have supplanted confidence and exertion and by many indications, we have reason to apprehend that too many of our legislators have drank deeply at this destructive fountain.

We cannot, however, suffer ourselves to indulge the belief, that the representatives of an enlightened community, jealous of their liberties and lynx eyed with respect to their interests, will be permitted (if they should be so disposed) to abandon one of the most important interests of the state, and suffer the exertions to improve our agriculture, to droop and expire for want of judicious and timely aid. They cannot be permitted nor is it to be believed, that they will be disposed to forget or neglect that true, just saying of Vattel, "The sovereign ought to neglect no means to render the land under his jurisdiction as well cultivated as possible."

But I have already taxed your patience too long and must rely upon your candor to palliate errors. It is not unfrequently more judicious to call into action the powers and means already possessed, than to win theories which may prove of no practical importance.

Curious and simple manner of keeping Apricots, Peaches, Plums, &c. fresh all the year. By M. Lemery.

Beat well up together equal quantities of honey and spring water; pour it into an earthen vessel, put in the fruits all freshly gathered and cover them up quite close. When the fruit is taken out, wash it in cold water, and it is fit for immediate use.

FROM A CORRESPONDENT.

Substitute for White Lead.—Take the best Rhode Island lime, and slake with the smallest possible quantity of water: as soon as it is cool, add to it buttermilk (strained so as to free it from the butter,) in such proportion as will make it as thick as common white-wash be careful that it is free from lumps.—To be applied with a white-wash brush.

Substitute for Champagne Wine.—A very excellent substitute for Champagne wine is said to be made from the juice of unripe gooseberries with a (large) quantity of sugar, sufficient to render it sweet.

HANCOCK CATTLE SHOW.

Belfast, October 29, 1823.—The first annual Cattle Show, and Agricultural and Manufacturing Exhibition of the Society, for the County of Hancock, was held at Bucksport on Wednesday the 22d instant.

The several Committees, owing to the want of time, reported verbally. Official reports will be made hereafter, and published, if they should be found on examination to vary essentially from the statement which follows.—

The day being rainy, particularly in the morning, was very inauspicious to the Exhibition. Our section of the country having suffered much the past season by an unprecedented drought, great expectations were not indulged with regard to vegetable productions or agricultural experiments. The premiums offered by the Society were neither large or numerous. The show being a novelty in this county, many preferred being spectators at the meeting, rather than competitors for the premiums. Besides the prejudices of practical Farmers, and their attachment to ancient customs, are great obstacles to improvement in the science of Agriculture. Taking these difficulties and other local disadvantages into view, the Exhibition was as well attended and the Show was as respectable as its most sanguine friends ever anticipated.

In the morning the following Committees were chosen, and performed during the day the duties assigned them respectively, viz.

Committee on Stock.—Samuel M. Pond, Josiah Hook, Jr. and Daniel Spafford.

On working Cattle.—Leonard Jarvis, Joseph Lee and John Lee.

On Horses.—John N. Swazey, Benjamin Hook and Solomon Skinner.

On Vegetable Productions.—Hezekiah Rowell, Edward S. Jarvis and Thomas Adams.

On Discretionary Premiums.—Caleb B. Hall, Leonard Jarvis and Samuel Little.

M. S. Judkins was chosen Treasurer *pro tem*. The following Premiums were awarded by the Committees, and approved by the Trustees, viz.

- | | |
|--|------|
| To Col. John Black, of Ellsworth, for the best Bull, the Society's full premium. | \$10 |
| To John Pierce, of Prospect, for a pair of Working Cattle, a premium of | 5 |
| To Sewall Lake, of Bucksport, for ditto, | 3 |
| To Henry Little and others for the best Stud Horse, (the Rising Sun) the full premium, | 15 |
| To Daniel Edwards, of Brooks, for the next best (The Young Kentuckian) | 5 |
| To Enoch Page, of Bucksport, for a specimen of Italian Summer Rye, | 2 |
| To Benjamin Smith, of Surry, and William Page, of Frankfort, jointly, for the greatest quantity of wheat raised on an acre—to each, a premium of five dollars, | 10 |
| To Leonard Jarvis, of Ellsworth, for a specimen of cheese exhibited by him, | 3 |
| [This premium with one fourth of the sum awarded to the "Rising Sun" was returned by Mr. Jarvis to the Society.] | |
| To Gilbert Van Emburg, of Barncot-island, for the best Butter | \$5 |

We will proceed to hazard a few remarks on the animals and other articles exhibited. Col. Black's Bull was a very fine animal—large, exceedingly well formed, and of perfect points.—The owner not being present, we have been unable to obtain any accurate account of him. His pedigree, &c. will be furnished hereafter, and published.

The Horse *Rising Sun*, owned by Col. Little and others, is a valuable acquisition to this coun-

ty—not much noticed heretofore, for an excellent breed of horses. *Lightfoot* would not have been an inappropriate name for this fine horse—his gait and general appearance obtained great applause.

The young *Kentuckian* is a remarkably fine animal, only three years old—he possesses most of the points of a good horse.

An iron grey Horse, from Ligonja, in the county of Kennebec, was offered for exhibition.

We were very much pleased with his appearance. It is a favorite color among connoisseurs both for the carriage and the saddle. We understand this horse is to be kept a part of the time next season in this county.

In the trial of strength between the working cattle owned by Mr. Pierce and Mr. Lake, very considerable interest was excited. Against Mr. Lake's cattle there was at first no competition, and as the former were entered irregularly, discretionary premiums only were awarded to both claimants. The trial was made by drawing a swamp pine mast, cut last winter, which has remained with its bark on. The stick was fifty-five feet long, and seventeen inches mean diameter. It was drawn over uneven ground, with a chain attached to the top end. It was moved by both teams but the greatest distance by Mr. Pierce's oxen. It is to be observed however, that his cattle were shod while the others were not—besides the bark was considerably rubbed off by the first trial—both yoke exhibited great docility and were well trained. Those owned by Mr. Pierce were in the best order for working cattle, and their form more perfect than the others. We would recommend a Ploughing Match for another year.

Some swine of an improved breed were exhibited by the Rev. Mr. Blood and Mr. Lake. That of Mr. Blood's was a cross of the Chinese and Newbury whites. This kind fatten very easily. It has been much approved by Gen. Dearborn and others.

The specimen of Italian Summer Rye, cultivated and exhibited by Mr. Enoch Page, bids fair to be a valuable acquisition to our farmers. Our first object should be to render ourselves independent in the article of bread stuffs—and while it occurs to us, we will suggest, that in the cultivation of wheat, except in virgin soils, or crops from new lands, the use of Lime in considerable quantity, ploughed in as manure, will, we think, be found indispensable, particularly in stiff clayey soils. This Italian rye is much larger and whiter than the ordinary rye of the country—sixteen quarts of it were distributed by sale for cultivation. A further account of this article may be expected next year.

Some yearling native Bulls were exhibited by John Thurston of Sedgwick, and Benj. Doane of Bucksport.

The Butter exhibited by Mr. Van Emburg was very fine, and sold at auction for thirty one cents per pound. It will be seen by his account, which is herewith submitted, that his process for making it is essentially different from the common mode.—Having used this butter for some time, and knowing it to be of a superior quality, we can with confidence recommend his process to our dairy women—they will to be sure find it attended with some extra trouble, but the butter thus made will also be of enhanced value.

For the best managed Farm in the County,

and for experiments on Burnt Clay, Lime, and Plaster of Paris for manures, as also of various other articles, there were this year no application for the Society's premium. It is to be hoped in future our good farmers will volunteer in cause where failure is no disgrace, but the highest honor attends success. The encouragement of rural industry, by rewarding distinguished instances of agricultural experiments and improvements with a premium, is well worthy of attention, and although difficulties may exist with regard to its execution, the object should not be relinquished without some energetic attempt to accomplish it. The field of improvement is large, and the laborers are few—we have taken the first step—the step of all others the most difficult—our confidence of success is increased and our zeal is unabated. It will be recollected that our funds depend entirely upon annual subscriptions, and we hope this suggestion alone will induce the great body of yeomanry of this county to enrol their names among the list members. Wherever agricultural societies have been formed on liberal principles, great improvements in that science have been the invariable result. By them a spirit of emulation is kindled, which added to a love of gain, produces the greatest exertion. So far as it has been practicable to ascertain the views of the members of the Hancock Society, no spirit of despondency prevails, but on the contrary, a unanimous design to continue the annual shows in some part of the county. It has been suggested that the town of Belfast, would be a suitable and convenient place for the next exhibition.

It is desirable on many accounts that those who excel in Domestic and Household Manufactures should exhibit the fruits of industry and ingenuity at these Annual Shows—they serve as models to others; excite a spirit of emulation and add considerably, by their variety, to the pleasures of the day. The manufacturer of satinetts, cassimere, and woollen cloth—the maker of carpeting, flannel, cotton and woollen hose, gloves, straw bonnets, hearth rugs, &c. would find their own interest consulted by sending these articles forward, as after the exhibition should they fail of obtaining a premium, they can be offered for sale at auction, free of expense, when they would generally command high prices in Cash. We particularly entreat our fair friends in this way to encourage our humble efforts another year.

The Address delivered by Samuel M. Pond Esq. was a sensible and judicious performance—abounding with useful remarks to the practical Farmer. We can only regret that the usual limits of an address of this kind did not permit him to touch upon a greater variety of topics, which doubtless occurred to his view while writing it. We understand the address is to be published, and it is to be hoped will be read by every practical Farmer in the county.

Mr. Van Emburg's direction for making Premium Butter.

The first object of the dairy woman is to keep every article used in the manufacture of Butter perfectly sweet and clean. Tin is to be preferred for pails and pans. These are to be scalded daily, and dried in the sun or by the fire.—In milking great caution is to be observed that no foreign ingredient gets into the pail.—Take the milk from the cows over night, after strain-

keep it perfectly cool, so that in the warm-weather it may not sour. On the morning milking, add the morning milk to that of the preceding night, without any additional heat—standing awhile, as soon as the milk appears to begin to change, churn it. In summer change generally takes place about ten o'clock; in cold weather it requires to be kept longer for this purpose, say to spring and autumn, the milk of the first mess may be kept till day following, and then it requires the addition of warm water to the milk, to bring it to proper temperature for churning. But in case is the milk to be heated except in the summer before described. Where the cows do not daily come to the salt water, a quantity of brown or fine salt is to be added to the milk before churning. The precise time for churning is to be carefully watched, and at the first indication of change [or sourness] let it be immediately churned in the usual mode. The churn should be furnished with a plug at the bottom, when the butter is well come, the butter is to be drawn off by taking out the plug—water of about half the original quantity of milk is to be poured into the churn, and the churning resumed and continued until the butter is entirely separated from the milk, which may be easily learnt by practice and observation. The butter is then to be taken out with a wooden ladle, and fine blown salt worked into it with the ladle—let it stand an hour, then poured over again in the same manner—the operation is to be repeated at the interval of an hour, two or three times, always with the use of a ladle, until the salt is thoroughly combined with the butter. It is then in a suitable state for moulding, or to be put down in stone pots or earthen kegs.

The pots or kegs being well scalded, a strong brine is then to be made of salt and saltpetre, having well strained the pots or kegs are to be set on the sides therewith, and fine clean salt sprinkled on as much as it will adhere—the butter is then to be well packed down and completely filled up by pouring on the top the brine of the pickle. The salt upon the side of the vessel prevents the butter from adhering to the bottom, and permits the pickle freely to pass to the bottom. The butter-milk thus made is of increased quantity and value from that of the ordinary mode, both for use in the family of the farmer, and the residue for feeding swine.

GILBERT VAN EMBERG.

Maroon Island, Oct. 1823.

FOR THE NEW ENGLAND FARMER.

EDITOR—If you think the following, or any part of it, worth publishing, you have it at my disposal.

It is well known that a great portion of the land in New England, and especially that which has not been cleared many years, is more or less obstructed with stumps, which are great obstacles to cultivating and improving it, besides a considerable waste of land. It is true that most kinds of hard wood stumps will in a short time decay; it may, therefore, be more the farmer's interest to let them perish of their own accord; but pine, that has arrived at maturity before being chopped, will remain sound and unimpaired for twenty years, and, in many instances, have been known to last fifty years. Therefore, stands the cultivator in hand to

rid himself of these intruders at the least expense. The common method of getting them up has been to dig round, cut off the large roots, then hitch four or five yokes of oxen and draw them up by main force, which is attended with an expense that the commonalty of farmers can ill afford. There have, however, been machines constructed which extract them at much less cost than digging, but which cannot be done short of ten or twelve dollars per acre. These objections to clearing land from stumps, are in a measure obviated by the following simple mode of preparing and burning: That is, have the stumps in the spring of the year dug round to the depth of six or eight inches with a common stub hoe, or what is better, an old adze, such as carpenters use; (a man in one day can dig two acres.) Let them remain to dry till a convenient time after haying; then split off a little of the outside of the stumps and kindle fires under the principal roots and carefully cover them with earth. In this way the fire will work under the body of the stump, and burn out a cavity. If it does not completely consume the stump, it is left in a condition for drying more speedily. Firing should be repeated as often as convenience and dry weather will permit, and in two, or at most, three years the stumps will be completely exterminated at less than one fourth the cost laid out in the ordinary way of clearing.

It may, however, be better policy, on some farms destitute of fencing stuff, to dig up the stumps in preference to burning stumps, as it is exceeded by no other wooden fence, for long standing and durability, when put to that use; and it is peculiarly adapted to stopping sheep without the addition of paling, which is necessary either on log fence or stone wall. R.

TO THE EDITOR OF THE AMERICAN FARMER.

ICE HOUSES—WITH ICE CLOSETS ATTACHED.

Highland, 24 October, 1820.

DEAR SIR—I herewith hand you a sketch of my ice closet attached to my ice house, which I recently described to you cursorily, and of which you requested a more minute description. Having tested its value, I can with truth declare it to be a most valuable appendage.—The citizen and farmer may both enjoy its comforts—the latter more particularly, will soon know its value, where he is deprived of the benefits of a good spring. The greatest importance, however, attached to its use, I conceive to be the preservation of fresh meats, which I have kept for three weeks, as sound and wholesome, as the day it was placed in the closet, being entirely free from the musty and clammy flavour which it is apt to partake of, when confined in the customary way on the top of the ice. The only danger I apprehended, was the fear of losing my ice sooner in the season, from the closet drawing its quantum of cold atmosphere from the ice; I am happy to find, however, that my house still contains a body of ice, although it was little more than half filled, and (from my absence,) very imperfectly rammed. The size of my house is twelve feet square, and in depth to the floor, there being a space of one foot underneath, sloped to the centre where there is a well of two feet, to receive any water which may pass from the ice. The closet is four feet in width, which affords

sufficient room for a private family—to enlarge it, would be drawing too largely from the ice which might occasion it to melt more rapidly. If it should be required of larger dimensions, (particularly for butchers to whom it will be invaluable,) I would advise that the house be enlarged in proportion. The pit is dug about three feet wider at top than bottom, the house being built perpendicular, (of logs or plank, mine is the former,) will leave a cavity eighteen inches wide at top, round the house, in which straw is to be closely crammed; this, with a layer of straw at bottom and straw mats laid over the top of the ice, will be quite sufficient for its preservation. The partition is made of the same materials the house is built of, observing not to join it too close, leaving the slightest opening so as to admit the escape of cold atmosphere into the closet, the top of which to be tightly closed up. The communication to the closet must be by a descent from one end of it to a door, to be cut immediately under the plate of the house, and from thence by a small flight of steps to the bottom of the closet, which is to be on a line with the bottom of the ice room, the top of the steps on the side to be secured by a sloping door; the lower door of the closet to be made only large enough to admit one person at a time, both tight, and to be opened as seldom as possible. The roof ought to project wide enough over the pit to secure it from the weather; where the ground is tenacious, I conceive it unnecessary to wall up the pit, but when this is not the case it will be the most prudent to do so.—I have been, I think, unnecessarily particular in the description, and if you agree with me, you can make use of such parts of it as may be thought requisite.

I have added also a ground and elevated view of the interior of the house, as it may serve to elucidate some parts of this hasty sketch.

I am yours,

Very respectfully,

J. S. WILLIAMS.

Ground View.

Elevated View.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR.—As your paper is almost exclusively devoted to the subject of agriculture, I beg leave to submit, through the medium of it, a few observations upon a subject which though long since introduced, and by some few claimed some small share of attention, is, perhaps, susceptible of as much improvement as any one branch of agriculture.—I allude to the subject of cutting hay, straw, &c. for fodder and other uses.

In the first place it is evident beyond a doubt that a great saving may be made by cutting hay—as by this means it is more generally mixed together—i. e. the best locks with the poorest—the heads, seed, leaves, stalks, &c. become a general mixture—so, that the animal cannot select the best locks, and tread the remainder under foot; as is frequently the case; especially when you would keep them full of feed and in high flesh. And as no farmer can avoid having different qualities of hay, he can cut a small quantity of good, with some of his poorer, indifferent quality, and thus mixed it will be as readily eaten as the best without cutting—or even take washed hay with a trifle of brine sprinkled upon it, or when it is to be had a small quantity of salt hay cut with it; and it is equal to, and will go as far as the average quality of hay fed in the common way. And if hay is scarce, as is often the case, add a portion of cut straw with the best quality of hay and when well mixed together it will go much farther by the addition of the straw.

I think that no one of any experience or observation, in feeding stock will attempt to deny these facts and that these alone would at least warrant the expense of the experiment. But notwithstanding the evident importance of what has been said respecting hay, it is still more evident that with the article of straw still greater savings and improvements may be made. In the first place it is universally admitted that cut straw mixed with meal or provender is an excellent substitute for hay, and in many cases supersedes the use of hay to those who have their fodder to buy, because the same expended for grain and straw (as the prices of hay and grain usually are) will go farther than it would if expended for hay—and prove better to those that raise their fodder, because more can be raised with the same expense.

But besides the utility of using it for fodder, it may be used with much more profit for manure by cutting it than it can without—for instead of throwing it, in large quantities, into the yard, as is usually the case, to undergo a decomposition by being exposed to the wet and dry weather through the summer season thereby losing one half or more of its real worth, which is carried away in the atmosphere to enrich the distant hills and mountains. I say instead of this, cut the straw fine and strew it liberally into your stables—it affords a soft and agreeable bed for your cattle which is very necessary in cold weather; it also absorbs and retains all the valuable moisture of stall and droppings of the cattle and prevents it from freezing in large and troublesome heaps to the floor, and is easily shovelled out and mixed with the stable manure and no doubt adds to the value of the manure exclusive of the addition of the straw and is much more fit for use in the spring by reason of its fineness and capable of being more equally

spread and mixed with the soil, besides being doubled in quantity and quality by the addition of straw; or if more is raised than can be disposed of in this way supply your hog-sties with it; or even if thrown into the yard, it abundantly pays the expense of cutting; for by sprinkling a small quantity of brine upon it, your cattle will eat more of it, than they would if it were whole; and the surplus is ready in the spring to be applied as manure; but if thrown out whole it is almost impossible to take it from the yard or spread it upon the land on account of its tough and entangled state.

It may also be used with great advantage by sowing it at broad casts over the fields either in grass or ploughing lands, the latter of which is preferable. It has a valuable effect, as by spreading it even and by ploughing it in, it mixes evenly with the soil and renders it light and fertile.

It furnishes an excellent manure for potatoes;—put a half peck, or more, of cut straw to a hill and your crop will be greatly increased and the land improved for the next crop in consequence of it.

That straw is worth five or ten times more for manure by being applied before rotted is evident beyond a doubt from the fact that stubble when turned in immediately after reaping, will not only support a long succession of crops, but will actually improve the soil. But when it is suffered to remain standing six or eight weeks, it is well known that it is much lessened in value and that a short course of such practice will unfit the land for cultivation unless sustained from other sources.

Oats in the sheaf may also be cut to great advantage as it is cheaper than threshing and makes more consistent food than oats alone.

The foregoing observations are made with a view to excite a greater attention to this subject. If they have this effect upon the farmer, I shall feel myself amply rewarded for my trouble.—satisfied, as I am, that when he has made a fair and thorough experiment he will no longer adhere to the course pursued, in this respect, by his father and grandfather. A SUBSCRIBER.

NEW ENGLAND FARMER.

SATURDAY, NOVEMBER 15, 1823.

THE PRESERVATION OF ICE.

In a preceding page of this day's paper we have given an article, (copied from the American Farmer) on the construction of Ice Houses, which we believe will be found worthy the attention of all who wish to preserve that article, especially in cases where a closet for the preservation of fresh meat is wished to be attached to the premises. We would suggest in addition the convenience and utility of making use of carpenter's or joiner's shavings instead of straw for the preservation of the ice. We are assured by gentlemen of the first intelligence and respectability, who have repeatedly tried the experiment, that shavings are much superior to straw for the purpose of surrounding and covering the ice which you wish to preserve. Ten or twelve tons of ice preserved in shavings have been found to go farther and last longer than three times that quantity, when straw was made use of. It is hardly necessary to add that shavings generally cost nothing but the trouble of their removal, and application, but straw costs something, and is worth something for other purposes.

Those persons who may wish to preserve ice, and are unable or unwilling to be at the expense of constructing ice houses, may, perhaps, derive some advantage from the following extract from an "Address to the Essex Agricultural Society, by Andrew Nichols, Esq." which states a mode of keeping ice in a common cellar; and which we republish from our first volume p. 114, for the benefit of those among our subscribers who may not be in possession of that volume.

"In the middle or one corner of the cellar may be built a bin. Throw down some boards, and cover the bottom with straw; or what is better, the spent bits of tanneries, generally known by the name of tan, sufficient quantity to leave it a foot in thickness under the common pressure. In the month of February, March, go to the most convenient pond of fresh water and obtain a sufficient quantity of ice, cutting or sawing it up in blocks as large as can be conveniently handled, and pile it up as compactly as possible in the bin, leaving a space of one foot or more all around it; fill this space, and cover the whole with tan straw, [or shavings] and the ice, unless the cellar is uncommonly open will keep the whole summer. Ten men, and one pair of oxen, will perform all the labour necessary to lay in such a store of ice in one day. Around this ice let the pans of milk be set, and place the pots of cream and butter upon it. Place two or three pounds of ice in each box when the butter is sent to market."

MR. FESSENDEN.—Having prepared for the Trustee of the Massachusetts Agricultural Society a list of 10 Towns in this state which received premiums at our late Brighton Show, I was directed by them to publish in your next "Farmer"—it will prove to our country friends, that although our funds are derived wholly from subscriptions in Boston and its immediate vicinity yet a very trifling part of the premiums are awarded near our "Head Quarters" but are diffused very generally through the state.—It is also to be recollected that a large additional sum is yet to be awarded in December for Agricultural Experiments and Crops, which will principally go to the interior towns.

Those persons to whom premiums were awarded at the late show and have not received them, are requested to call on the Treasurer for the same and to be in mind that if not called for within six months, they will be forfeited and abandoned to the use of our Society.

JOHN PRINCE, T. Assr.
of the Massachusetts Agricultural Society.

FOREIGN.

Capture of Cadix.—The report of the capture of Cadix is confirmed. Capt. Davis arrived at New York on the 10th inst. from Gibraltar, which last mentioned place fell on the 5th October. He states that the rejection continued for two days along the coast, and that French vessels at Gibraltar fired and displayed the red and Spanish flags in union.

Greeks.—Great efforts are making to induce the nations to interfere in behalf of the Greeks in their national struggle against Turkish oppression, and said that the prospect is promising—that the aid will not be ineffectual. A deputation sent by London Greek Committee to the Morea, had received, and made a most favorable report, and were in train to excite powerful and generous emotions on the part of the British in behalf of the efforts of a renowned nation struggling to be emancipated from the most merciless despotism that ever degraded the human race.

Vera Cruz.—This place has been bombarded several times the 25th ult. From 12 to 15,000 shot shells have been thrown in the castle from the many houses injured, some torn to pieces, and 100 persons killed. The fire was returned from within shot, shells and grape. The city is shelled, and the governor of the castle has confined Spanish merchants.

Peru.—Former accounts left the Spanish ships in possession of Lima, but they remained only a few days in that place, and evacuated it on the approach of the independent allied army. The Spanish ships, Canteana and Laserna, retreated into Upper Peru with about 14,000 men having previously levied a contribution of \$300,000 on the city, burnt the Mint and other edifices. Generals Santa Cruz, and Suñer, 12,000 men were about to follow. Bolivar, who arrived at Guayaquil, was occupied in sending reinforcements to the independent army.

Spain.—The ship Galathea, Captain Smith, arrived at this port on the 12th inst. and brought English papers to the 11th Oct. giving an account of occurrences at Cadix, during some of the days of the siege. At the last meeting of the Sept. 29, no more than five Deputies could be admitted, and they, after imploring the clemency of the king, declared that he was re-established in the independence of his royal powers. The fate of Cadix is not known. He entered Madrid as a prisoner, on the 24 Oct. and the kisses of the populace. Spain has at length regained the independence of her colonies in South America.

DOMESTIC.

Produce County Show.—One of our agriculturists in the County of Grafton writes to us,—"The Agricultural Society held their annual Exhibition Fair, at Lyme, on Wednesday the 1st inst. It was in general, though not numerous, was of the quality, and the same may be said of the Domestic manufactures. The large concourse of independent practical farmers assembled on the occasion did great delight with the various exhibitions of hay, and particularly with the very able and practical address from Professor Dana. We understand the society have requested a copy for the year, and I sincerely hope the public will speedily be satisfied with its perusal. A regular account of the society's proceedings will soon be communicated in the Patriot.—N. H. Patriot.

Potatoes.—The Fayetteville, N. C. Observer writes that the past season in a garden town, which was one foot in length, 17 inches in circumference, and weighed seven pounds and eight

Beet.—A Blood Beet, raised in Mr. Seymour's garden in Salem, N. Y., weighed 11 lbs. 12 oz. and 25 inches in length, and 22 inches in circumference.

Apples.—An apple was lately picked from a tree in Mr. Walling's farm in Hartford, N. Y. which

weighed 20 1-2 ounces, and measured 14 1-2 inches in circumference. Mr. Joseph Ingalsby of the same town, picked one from a tree in his garden weighing 22 ounces. The Troy Sentinel says that "an apple was brought to our office last week measuring 15 1-4 inches round, and now weighs 21 ounces; when taken from the tree about three weeks since, it weighed 23 ounces. It was raised on a farm situated a few miles from this city, the property of one of our neighbors."

Indian Corn.—Fall Ploughing for Indian Corn is recommended by the President of the Pennsylvania Agricultural Society, as a sure preventative against the grub or Cut Worm—and he has published several facts corroborating the same.

Lime Stone.—A large bed of lime stone has been recently discovered in Bedford, N. H. It is believed by those who have examined it, that it will answer all the purposes as cement for building or for manure. [New England Galaxy.

New kind of Manufacture.—A Miss Brengle lately exhibited at Georgetown, N. C. proofs of wonderful skill in the use of Scissors. In a piece of paper an inch square, she cut out the letters that compose the Lord's prayer in a style of elegant typography. Every letter was accurately formed.

The New York Post states upon the faith of information recently received from England, that Mr. Perkins calculates making a trip to the United States, in ten or twelve days, in the new steam ship which he is constructing. This will be a most astonishing step in the science of Navigation—so astonishing from the rapidity of the advance, that a century would seem necessary to make it. The achievement would immortalize the name of Perkins. It would be more famous than the expedition of Jason and the Argonauts. It would be bringing as it were the two continents fifteen hundred miles nearer together. It would communicate intelligence of distant events with a velocity which no man twenty years ago could even have dreamed within the range of possibility. It will form a new era in the world—as great as the discovery of the mariner's compass. The consequences it would produce would baff all calculation. Should it succeed, it will bind a new and never fading wreath, round the brow of our country.—Richmond Compiler.

The whole amount of premiums awarded by the Hampshire, Franklin, and Hampden Agricultural Society at their late exhibition, is \$704—\$78, of which, were awarded to persons living within the bounds of Franklin county—\$141, to persons living in Hampden county—\$45, to persons living in Hampshire county. [Greenfield Gazette.

American Tea.—Mr. Mallet, of Louisiana, has succeeded in raising Hyson Tea from the seed; and has now an extensive bed of the shrubs.

Cabbages.—On Mr. C. Russell's farm, New Bedford, 1200 Cabbages, five of which weighed 122 lbs. were produced on 60 rods of ground. They were planted three feet apart.

Industry.—The following statement of the work bestowed on the Gipsy Bonnet which sold at the late New York fair for \$100, is from Miss Julia Harrison—the maker:—

Eleven days in preparing and cutting the straw—48 days in braiding the same—34 days in sewing the same—120 yards of braid in the hat—258,000 times turned or handed in braiding—236,000 separate stitches in sewing, which is 2400 stitches in each yard—65 rows around the front—7 inches in the front—9 2-7 braids to the inch—13 straws in the braid—2 1-2 yards is a day's work at braiding—4 yards is a day's work at sewing.

Longevity.—On Monday last, (says the Clarendon, N. H. Spectator) Mrs. Elizabeth Parker entered her 100th year. On this occasion the Rev. Mr. Nye preached a sermon to a crowded audience. Mrs. Parker was born in Cheshire, Conn. has been twice married, and has had twelve children, only two of whom are living.

Casualty.—On Monday of last week, Mr. Willard M. Bridges, of Sunderland, having been at work at a napping machine, carried by water, was in the act of hanging up the band to it, when his foot was caught in the band, and he was drawn over the drum and carried round with it several times, before he could be liberated, which so bruised his head and body, that he expired in about three hours.—Ath inst.

Fire.—On the night of the 23d ult. a Woollen Factory, in Cummington, belonging to Darius Ford, of Cummington, Mass. was destroyed by fire. The damage sustained is estimated at about \$3,000.

Salt Works.—In a few years upwards of a million of bushels of Salt will be manufactured in the county of Onondaga, N. Y. the duties on which at 12 1-2 cts. per bushel, will amount to \$125,000 annually, which, with the tolls of the canal, are forever appropriated to the canal debt, and will soon liquidate the whole sum. The gross income in a few years, may be about \$300,000.—Albany Argus.

A Beet raised by D. Stinson, Esq. of Bath, Maine, measured 27 inches in length, was 27 inches round, and weighed without the top nine and a half pounds.

HEALTH AND INDUSTRY.

Ah! what avail the largest gifts of Heaven
When drooping health and spirits go amiss?
How tasteless then whatever can be given!
Health is the vital principle of bliss,
And exercise of health! In proof of this,
Behold the wretch, who slugs his life away,
Soon swallow'd in disease's dark abyss;
While he whom toil has braced, or manly play,
Has light as air each limb, each thought as clear as day.

O who can speak the vigorous joys of health?
Unclogg'd the body, unobscur'd the mind;
The morning rises gay; with pleasing stealth,
The temperate evening falls serene and kind.
In health the wiser brutes true gladness find;
See! how the younglings frisk along the meads,
As May comes on, and wakes the balmy wind;
Rampant with life, their joy all joy exceeds?
Yet what but high strung health this dancing pleasure breeds?

It was not by vile loitering in ease
That Greece obtain'd the brightest palm of art,
That soft yet ardent Athens learnt to please,
To point the wit, and to sublime the heart!
In all supreme! complete in every part!
It was not thence majestic Rome arose,
And o'er the nations shook her conquering dart,
For sluggard's brow the laurel never grows!
Renown is not the child of indolent repose.

Had listless mortals paid regard to nought
But in loose joy their time to wear away;
Had they alone the lap of dalliance sought,
Pleas'd on her pillow their dull heads to lay,
Rude nature's state had been our state to day;
No cities e'er their towery fronts had rais'd,
No arts had made us opulent and gay;
With brother brutes, the human race had grazed,
None e'er had soared to fame, none honor'd been, none praised.

MISCELLANY.

SPANISH INQUISITION.

This horrid tribunal was first instituted by Pope Innocent III, about the year 1200.—Its first efforts were directed against the Albigenses in the south of France; and in no long time it found its way into almost every country in Europe (Great Britain excepted,) where popery was the dominant religion. The most active and celebrated of these tribunals was the SPANISH INQUISITION, which by an unaccountable perversion of language has been termed the *Holy Office*. It was first introduced into Spain about the year 1231, and was sufficiently active and intolerant in that country until 1481, when Ferdinand V, and Pope Sixtus IV, established what is called the modern Inquisition, under the direction of Inquisitors General, with a host of subordinate officers. The history of this detestable court, has been written by various authors; but the most authentic, is that of the late M. Florente, in four thick octavo volumes drawn from the archives of the Inquisition, of which he had been Secretary. This work has very recently been abridged by M. Gallois, from whom we have translated the following general totals of the number of the victims of the Inquisition in Spain, under

45 Inquisitors General, between the years 1481 and 1820.

Burnt alive	34,658
Burnt in effigy	18,019
Condemned to the gallows or imprisonment	288,214

The sum total, therefore, of the victims of the Inquisition in Spain, between 1481 and 1820, amounts to three hundred and forty thousand eight hundred and ninety-one exclusive of a considerable number of persons who have been imprisoned, condemned to the galleys, or exiled from Spain, under the reign of Ferdinand VII, the present imbecile sovereign of that unhappy country. What cruelties may not be expected, should despotism ultimately be re-established there? For it should never be forgotten, that tortures of the most horrid kind form a part of the regular system of the Holy Office. If to the condemnations which have taken place in the peninsula, during the period above noticed, we add those of other countries subject to the Spanish Inquisition, as Sicily, Sardinia, Flanders, the Canary Islands, South America, the Indies, the number of victims condemned by this tribunal would be truly appalling.—Not only has the Inquisition decimated the population of Spain by its *autos-da-fe* (or acts of faith,) but it has also considerably reduced that population by the civil wars and commotions which it has provoked, and especially by procuring the expulsion of the Jews and Moors from that country. More than five millions of inhabitants have disappeared from Spain since the Holy Office has exercised its terrible ministry. Verily, "THE TENDER MERCIES of the wicked are CRUEL!"

Qualifications for Congress.—"Why do you not present yourself as a candidate for Congress?" said a lady the other day to her husband, who was confined to his chair by the gout, "Why should I, my dear?" replied he; "I am not qualified for the station." "Nay, but I think you are," returned the wife; "your language and actions are truly parliamentary." When bills are presented, for instance, you either order them to be laid on the table, or you make a motion to rise; though often out of order, you are still supported by the chair; and you often poke your nose into inclosures which are calculated to destroy the constitution?

The old adage that "the eye is often bigger than the belly" is verified by the ridiculous vanity of those who wish to make an appearance above their fortune—nothing can be more ruinous of real comfort than the too common custom of setting out a table, with a parade and a profusion, unsuited not only to the circumstances of the Host, but to the number of the guests;—or more fatal to true hospitality than the multiplicity of dishes which luxury has made fashionable at the table of the great, the wealthy—and the ostentatious,—who are often neither great nor wealthy.

Economy.—A useful hint to young men.—For your own comfort, for your friends' solace, for the sake of your eventual prosperity, cultivate a strict and manly habit of Economy. It is impossible to raise a good character without it. And this one single article, connected with a moderate talent, will recommend you to all with whom you are to have any transaction from whom you may obtain confidence, or expect re-

muneration. Assistance should you need it, not be withheld, if it is known that your personal expenses are correct.—

* * * Do not esteem the name of Economy a trifle. Do not account the practice a mean. Generous, free, call it what you will, terms which do not apply, unless it is liter and truly your own money which you are saving; nor then if you sport more than your means and circumstances prudently warrant.—Taylor

War costs more than it comes to.—Archbishop Fenelon, when most in favour with Louis Fourteenth, used to say, "I would rather the King lose half his dominions, than occasion a battle in which the lives of many citizens would be thrown away."

Manners make the Man.—Good manners have often made the fortune of many who have nothing else to recommend them: Ill manners have as often marred the hopes of those who had every thing else to recommend them.

Act for and speak of every body as if it were present and you will have nothing to apprehend from the tale bearer.

Golden Rules for Men of Business.—Do everything at the proper time. Keep every thing in its proper place. Use every thing for its proper purpose. Never think any part of your business too trifling to be well done.

A foolish fellow, when addressed by a marquis, used to answer, "thank God and your lordship." "How many children have you my lord?" said a Grandee to him: "Four the God and your lordship."

Poverty.—Resolve not to be poor; what else you have spend less. Poverty is a great enemy to human happiness; it certainly destroys liberty, and makes some virtues impracticable, and others extremely difficult.

A "high flown" Writer.—It was well said of a certain learned but obscure Author that his productions were

"Like stars, when of too great a height
They give us neither heat nor light."

We are informed that, a few days since, Molly Miles, a colored woman, one hundred and four years of age walked to Kennebunk, a distance of about 30 miles!—Portsmouth, N. H.

Generating Steam.—A plan "for applying Electricity, Galvanism, or burning glasses, to the generation of Steam," has been announced by Mr. Slack, in the Rhode Island American. He thinks burning glasses would be a cheap way for Farmers to do their boiling and cooking and says that the expense of the apparatus would be comparatively trifling.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at discretion of the publisher,) until arrearages are paid.

No. 17.

Farmers and Gardeners's Remembrancer.

[BY THE EDITOR.]

MANURE YOUR GRASS GROUNDS.

Intelligent and scientific cultivator, who a number of valuable articles, which are inserted into Messrs. Wells & Lilly's edition of *Deane's Geographical Dictionary*, has given following remarks on this subject, under ad "Top-Dressing," in that work. There is scarcely any question, on which we are more divided than as to the policy of using manure as a top dressing to grass lands, spring or fall. The reasoning seems to favour of spring dressing, and it is supported by many excellent names. But it ought known, that intelligent farmers, near the cities, most generally dress their lands in autumn. Besides the reason stated above, that lands are less injured by carting over them in fall; it may be added, that it is a season of winter leisure; and although it is confidently asserted, that the manure is wasted by rains or snow, yet much ought to be allowed on the side, for the protection afforded by the dressing to the tender roots of the plants in winter, and ought we not to add somewhat for the low temperature of the atmosphere in winter, which prevents evaporation? The principles of fertility exist in manure, winter carried down into the soil. We are fully convinced that a scorching sun, and a dry air, are more pernicious to manures, thinly over the surface than any drenchings can be, unless on declivities where top dressings are unquestionably of less value than on level grounds. The fact that farmers who, by supplying the great towns with manure, generally adopt the practice of fall dressing their grass lands deserves weight. "Top dressings should not be used in the fall on winter grain, because they would be apt to kill the young plants come forward too fast, and so rank that they would be liable to winter killed. Top dressing for wheat, rye, &c. should be applied to the growing crop in spring or early in the summer, when it is evident that the land is not rich enough to support a full crop to perfection.

As to the materials for dressing grass grounds, after your garden is supplied with manure, you may as well cart on to your mowing land all that you can collect from your yards, your stercoraries or dung heaps, manure, compost beds, night soil, &c. &c. &c. A good deal of dung, however, before being applied to grass land should be well mixed with loam. Of some kind of earth which will imbibe the gas or effluvia of the dung or putrescent manure. We have said before, in substance, that the use of putrescent manure, (that is, those vegetable substances which are liable to putrify, mould, and be wasted when exposed to the sun and air) are in a great measure wasted away, if applied to the surface of the land before being made into compost. "Spread putrescent substances upon the surface of a

field of grass ground, is to manure not the soil but the atmosphere; and is justly condemned as the most injudicious plan that can be devised in an arable district."* If dung not made into compost nor mixed with earth or any substance which will attract and imbibe its gas, effluvia, volatile products, or (to be more plain) that which causes it to smell unpleasantly, be applied to a field of plough land, it ought to be spread evenly and ploughed, or at least harrowed in immediately. If a farmer's chief dependence is in grazing land, and he has dung, or putrescent manure not made into compost, to apply, we would suggest it for his consideration whether it might not be well, first to spread his dung as evenly as possible over his field, and then spread over the whole at least an equal quantity of good earth or loam. By such means a compost is made in the field after the putrescent manure is applied, and the earth or loam spread over the dung, will not only absorb its gaseous products but in a great measure protect it from being dried by the air or scorched by the sun, till its fertilizing qualities are dissipated. This method of managing with top dressing for grass land, however, we should suggest merely as an expedient for the saving of labour in cases, where farmers have much dung, but little plough land in proportion, and with whom the saving of labour is a very great object. As a general rule, the following maxim of Sir John Sinclair will apply as well in this country as in Great Britain. "There are strong objections to the application of dung to grass lands, (much of its strength being evaporated, from its being exposed to atmospheric influence,) composts are greatly to be preferred. They may be applied, at the rate of from 30 to 40 cubic yards per acre. To keep grass land in good condition, a dressing to this amount is required every four years. The application of unmixed putrescent manure will thus be rendered unnecessary."

The mode in which some farmers manage with regard to manuring their grass lands is not only absurd but ruinous. Early in the fall they cart their dung from their barn yards and styes, which perhaps had been a year or more accumulating, and of course is finely pulverized and ready to take the wings of every breeze. They place it on a tough sward in little heaps about the size of a two bushel basket. The sun, high winds, rain, and drying atmosphere, all conspire to rob these little heaps of nearly all their fertilizing qualities and leave little but a dead mass of matter as "dry as a husk." Late in the spring, and generally during, or just before a dry time, Mr. Cultivator spreads these little heaps, (reduced by exposure to wind and weather to about the size of a half bushel measure) over the sward. If the season proves dry, the manure particularly that part which was collected from the stye has scarcely any other effect than to assist the sun in scorching the grass. In the mean time the arable land, being left destitute of manure for the sake of *dunging* the grass ground yields not half a crop. The poor farmer believes his land worn out, and thinks it high

time to "pluck up stakes and be off to the Ohio!"

Unless you have plenty of manure, you had better not apply any dung to your high, gravelly or sandy soils, but dress them with plaster of Paris. "Uneven grass grounds will not admit of top dressing to any advantage, on account of the manure's being liable to be washed away.

Previous to manuring your grass lands it will be well to harrow or scarify them. "Rolling was formerly considered to be indispensable in the management of grass lands, tending to smooth and consolidate the surface;—to prevent the formation of ant-hills;—and to render the effects of drought less pernicious. But *scarifying* the turf with a plough, consisting only of coulter or harrow teeth, so that the whole surface may be cut or torn is to be recommended when the pastures (or mowing land) are hide bound. That tenacious state, rolling tends to increase; whereas by scarifying, the surface is loosened, and the roots acquire new means of improved vegetation. This operation seems particularly useful, when it precedes the manuring of grass lands; for if well scarified, the ground is so opened, that any manure spread upon it gets at once to the roots, consequently a small quantity thus applied, goes as far as a larger one laid on in the old mode, and without such an operation. Thus the force of the objections to the application of putrescent manure to grass lands is, in some degree obviated."* After such process it may be well to sow grass seeds, to produce a new set of plants, and supersede the necessity of breaking up the soil to prevent its being "bound out" as the phrase is.

It is a bad practice to feed your mowing land very closely in the fall. There should be enough of the after grass left to protect the roots of the grass against the frosts of winter. We have known good farmers who would not suffer their mowing land to be pastured at any time of the year. But if the soil be well dressed with manure it can do but little or any injury to pasture in the fore part of autumn, taking care not to let cattle run upon it when wet, and so soft that they would make much impression on it with their feet.

* Code of Agriculture.

FODDERING CATTLE.

"We should take care not to begin to fodder till it is really necessary: Because cattle that are foddered, will not graze so diligently. When it is once begun the cattle will expect it, and it must be continued. When we first begin, we should fodder early in the morning only; for at that time of the day frost is usually on the grass so that the cattle will not graze. They should not yet be housed [that is in the beginning of November, or when the cold is not quite severe] horses excepted: But in wet weather the whole stock should be housed; for they bear the cold better than wetness, or if not put into the barn, they should have a shed in the yard, under which they may shelter themselves."

The meanest fodder should not be dealt out first of all. Husks and stalks are suitable for this season. The straw and worst hay should

be reserved to give them in the coldest weather; for it is then that they have the keenest appetites."

All sorts of cattle that chew the cud, as sheep, cows, &c. do not like either to graze after each other nor to eat one another's leavings in the foddering yard. But cattle that do not chew the cud will eat after those which do, and vice versa.

Moveable racks, if made so strong as not to be easily overturned are best for foddering from, because they can be easily lifted up as the dung or snow rises. It is best, however, to place such racks under sheds as well to shelter the cattle as to preserve the manure from the weather, which will be dropped in the largest quantities near the places where the cattle are fed.

"There is a remarkable difference in cattle's eating straw when fresh threshed, and when it has been threshed several days, especially if the straw is but indifferent fodder."* We believe, however, if fresh threshed straw is cut with hay of a pretty good quality, the whole sprinkled a little with a pretty strong brine, or fine salt and permitted to lie in a heap for several days it will improve in quality.

Much chaff and straw that is often thrown away, may with a little pains be made good fodder for cattle, by being mixed with green corn stalks or good hay, the greener the better, cut with a machine, sprinkled with fine salt, or brine, if the mixture will bear wetting. The sweetness of the stalks and hay are imbibed by the chaff and straw and the whole will make a compound very agreeable to cattle. They should not, however, be confined wholly to salted food but have fresh messes a part of the time.

When young animals are pinched for food at an early period of their growth, or fed with such as is not of a sufficiently good quality, they never thrive so well afterwards, nor make so good stock. Young's Farmer's Calendar says, "In the winter, the yearlings should be fed with hay and roots, either turnips, carrots or potatoes, mangel wurtzel or ruta baga, and they should be thoroughly well fed, and kept perfectly clean by means of litter. At this age it is matter of great consequence to keep such young cattle as well as possible; for the contrary practice will stop their growth, which cannot be recovered by the best summer food. If hay is not to be had good straw must be substituted, but then the roots must be given in greater plenty, and with more attention. To steers and heifers two years old, the proper food is hay, if cheap, or straw, with baits of turnips, cabbages, potatoes, &c. It is not right to keep yearling calves and two years old together, because in general the younger cattle are, the better they should be fed."

* *Lister's Husbandry.*

(TO BE CONTINUED.)

[From Knight on the Apple and Pear.]

ON PRUNING ORCHARDS.

The apple tree, being naturally very full of branches, frequently requires the operation of pruning; and when properly executed, great advantages will be found to arise from it. But as it is generally performed in Herefordshire, the injury the tree sustains is much greater than the benefit it receives. The ignorant pruner gets into the middle of it, and lays about him to right and left, till he leaves only small

tufts of branches at the extremities of the large boughs. These branches, now receiving the whole nourishment of the tree, of course increase rapidly, and soon become, when loaded with fruit or snow, too heavy for the long naked boughs to support, which are of necessity full of dead knots from the former labors of the pruner. Many hundred trees annually perish from this cause. The present system of pruning ought to be precisely reversed; and the pruner should confine himself almost entirely to the extremities of the bearing branches, which are always too full of wood, and leave the internal part of the tree nearly as he finds it.

In pruning the apple tree, and all other standard trees, the points of the external branches should be every where rendered thin and pervious to the light; so that the internal parts of the tree may not be wholly shaded by the external parts: the light should penetrate deeply into the tree, on every side; but not any where through it. When the pruner has judiciously executed his work, every part of the tree, internal, as well as external, will be productive of fruit; and the internal part, in unfavorable seasons, as I shall have occasion to remark when speaking of blights, will rather receive protection than injury, from the external. A tree, thus pruned, will not only produce much more fruit, but will also be able to support a much heavier load of it, without danger of being broken; for any given weight will depress the branch, not simply in proportion to its quantity, but in the compound proportion of its quantity and of its horizontal distance from the point of suspension; by a mode of action similar to that of the weight on the beam of the steel-yard; and hence a hundred and fifty pounds, suspended at one foot distance from the trunk, will distress the branch which supports it, no more than ten pounds at fifteen feet distance would do. Every tree will therefore support a larger weight of fruit, without danger of being broken, in proportion as the parts of such weight are made to approach nearer to its centre.

Each variety of the apple tree has its own peculiar form or growth; and this it will ultimately assume, in a considerable degree, in defiance of the art of the pruner. Something may nevertheless be done to correct whatever is defective. When the growth of any variety is weak and reclining, the principal stem should be trained to a considerable height, before it be allowed to produce branches; and if any of these take an horizontal, or pendent direction, they should be regularly taken off. One principal leading stem should be encouraged almost to the summit of the tree, to prevent a sudden division into two large boughs, of nearly equal strength; for the fork which these form, is apt to divide and break, when the branches are loaded with fruit. All efforts to give the heads of young trees a round and regularly spreading form, whilst in the nursery, will be found injurious in the future stages of their growth. Large branches should rarely, or never be amputated.

I would not be understood to disapprove of judicious pruning; on the contrary I think it ought very frequently to be done; but the tree ought always to retain, internally at least, much of the close branching growth, which its nature

always gives it. The pruning knife may, however, be used with some degree of freedom on young trees, for the branches of these soon pair any breaches which may be made in them but if an old tree, or one which has ceased to grow larger, be so thinned as to admit a current of air through it, it is ruined for ever. It has been supposed that the fruit, which stood exposed to the sun and air on the outside of branches, is alone capable of making fine cider but experience by no means justifies this conclusion. When a tree has been pruned according to the preceding directions, the fruit, on every part of it, will be found to possess very nearly the same degree of excellence.

CATTLE SHOWS.

Northampton Cattle Show.—We have already page 119, given a brief sketch of the late Cattle Show, &c. held at Northampton, under the auspices of the Hampshire, Franklin, and Holden Agricultural Society. The premium awarded on that occasion were as follows:—

ON ANIMALS.

To Isaac C. Bates, of Northampton, 1st premium for Bulls,
To Francis Graves, of Sunderland, 2d do.
To Noah Shearer, of Palmer, 1st premium for a bull calf,
To Moses Warner, of Hatfield, 1st premium for a milch cow,
To Joel Smith, of Hadley, 2d do.
To Theodore Bridgman, of Belchertown, 1st premium for two years old heifers,
To Asahel Strong, of Northampton, 2d do.
To Theodore Bridgman, of Belchertown, 1st premium for one year old heifers,
To James Shepherd, of Northampton, 2d do.
To Isaac Graves, of Sunderland, for working ox to Samuel Buffington, of Worthington, for do.
To Ezekiel Gomer, of Worthington, for do.
To Ebenezer Stebbins, of Deerfield, for cattle fed for the stall,
To Henry Hitchcock, of Hatfield, 2d do.
To Henry Hitchcock, of Hatfield, 3d do.
To Samuel Buffington, of Worthington, 4th do.
To Edwin Clark, of Northampton, 5th do.
To Theodore Clap, of Northampton, 6th do.
To Jedediah Taylor, of Westfield, 7th do.
To John Field, of Conway, 8th do.
To Moses Nash, of Williamsburgh, 1st premium for three years old steers,
To Elisha Strong, of Northampton, 2d do.
To Stephen Tower, of Cunningham, 1st premium for two years old steers,
To Austin Smith, of Sunderland, 2d do.
To Roland Burbank, of West Springfield, 3d do.
To Theodore Bridgman, of Belchertown, 4th do.
To Asahel Pomeroy, of Northampton, 5th do.
To Lewis Hubbard, of Hadley, 1st premium for one year old steers,
To Cephas Clark, of Northampton, 2d do.
To Noah Shearer, of Palmer, 1st premium for the best steer calf,
To Noah Shearer, of Palmer, 2d do.
To Nathan Tyler, of Chesterfield, 1st premium for a heifer calf,
To Nathan Tyler, of Chesterfield, 2d do.
To Isaac C. Bates, of Northampton, for merino b.
To James Shepherd, of Northampton, 2d do.
To Isaac C. Bates, of Northampton, for five merino ewes,
To John A. Judd, of Westhampton, 2d do.
To Asahel Pomeroy, of Northampton, premium for native ram,
To the same for five native ewes,
To Parley Wilson, of Northampton, for a boar,
To James Shepherd, of do. for do.
To Oliver Smith of Hadley, for sows,
To Thomas Lyman, of Northampton, for do.
To Frederick Hunt, of do. for the best litter of

ON MANUFACTURES.

 14 To David Edwards, of Northampton, for calf skins,
 15 To Samuel and Elisha Dickinson, of Hadley, do.
 16 To George H. Sylvester, of Chesterfield, do.
 17 To Ira Atkins, of Northampton, for harness work,
 18 To John W. Graves, of Easthampton, for boots,
 19 To the same for best shoes,
 20 To Dikeman and Shepherd, of Northampton, for
 21 fur hats,
 22 To the same, 2d premium, for do.
 23 To the same, 3d premium, for do.

GRATUITOUS PREMIUMS.

To Apollon Williams of Ashfield, for refined maple
 1 sugar,
 2 To Caleb Hannam, of Norwich, for steelyards and
 3 axes,
 4 To Quartus Kinsley, of Northampton, for Carpen-
 5 ter's tools,
 6 To Charles Smith, do. for cabinet tool,
 7 To Justus Wright, jr. do. for surgeon's instru-
 8 ments, &c.,
 9 To Nathan Storrs, do. for silver ware,
 10 To Mrs. Mary Montague, aged 90 years, of Gran-
 11 by, for stockings,
 12 To Sila Thorp, of Southampton, for mittens,
 13 To Mrs. Cynthia Thayer, of Greenfield, for com-
 14 mon hose,

ON PLOUGHING.

To Elisha Strong, of Northampton, first premium, \$10
 1 To Theodore Bridgman, of Belchertown, 2d do.
 2 To Francis Pratt, of Northampton, 3d do.
 3 To William Gaylord, of Amherst, 4th do.

ON BARN.

To Darius Nichols, of Brimfield, 1st premium, \$100
 1 To Robert Starkweather, of Chesterfield, 2d do.
 2 To James Shepherd, of Northampton, 3d do.

From the London Farmer's Journal.

ON FEEDING WITH MANGEL WURTZEL.

Kilton, Dec. 23, 1821.

Sir—I perfectly agree with your correspond-
 1 ent P.* in his answer to M. W. in your last Jour-
 2 nal, as to the value of Mangel Wurtzel as food
 3 not only for sheep, but also for bullocks, pigs,
 4 &c.; but experience has taught me that it should
 5 be used with caution at the commencement of
 6 feeding, that is, a small quantity only should be
 7 given; I therefore offer M. W. the result of my
 8 experience in the use of it.—The frost and
 9 snow of the winter 1820, depriving me of my
 10 other succulent food for my breeding ewes, I
 11 was obliged to make use of the store of Mangel
 12 Wurtzel, which was placed in troughs; hay was
 13 also allowed. Not having given any to ewes
 14 before, I was induced (in consequence of the
 15 Holkham cows being palsied a few years since,
 16 and having witnessed similar effects in my own)
 17 to notice particularly the effect: some of them
 18 fed voraciously; these, in a short time sickened,
 19 and in a few days began to lose their wool, and
 20 a part became quite naked; those were also the
 21 first that weaned their lambs in the spring. I
 22 would therefore recommend to M. W. to give
 23 his ewes near the time of lambing, and those
 24 recently lambed, but a small quantity, increasing
 25 it as the lambs increase in size, as experience
 26 has convinced me, that to create, by any suc-

1 lent food, the greatest possible flow of milk in
 2 the ewe, when the lamb is young and not able
 3 to draw the whole quantity from the udder is a
 4 bad practice of shepherding.

As Mangel Wurtzel stands, in my opinion, pre-
 1 eminent of all cattle crops, and having been a
 2 cultivator of it several years, and having tried
 3 several modes of cultivation, I intend the first
 4 opportunity, to detail for your service, the mode
 5 I found most successful. I am, Sir, Yours's truly,
 6 C. ADDAMS.

Method of Cleaning Silks, Woollens, and Cottons
without damage to their Texture and Colour.

Grate raw potatoes to a fine pulp in clean wa-
 1 ter, and pass the liquid matter, through a coarse
 2 sieve, into another vessel of water; let the mix-
 3 ture stand still till the fine white particles of the
 4 potatoes are precipitated; then pour the mucil-
 5 aginous liquor from the fecula, and preserve
 6 the liquor for use. The article to be cleaned
 7 should then be laid upon a linen cloth on a table,
 8 and having provided a clean sponge, dip it
 9 into the potatoe liquor and apply it to the arti-
 10 cle to be cleaned, till the dirt is perfectly sepa-
 11 rated; then wash it in clean water several times.
 12 Two middle sized potatoes will be sufficient for
 13 a pint of water.

Observations. The coarse pulp, which does
 1 not pass through the sieve, is of great use in
 2 cleaning worsted curtains, tapestry, carpets, and
 3 other coarse goods. The mucilaginous liquor
 4 will clean all sorts of silk, cotton, or woollen
 5 goods, without hurting or spoiling the colour;
 6 it may be used in cleaning oil paintings, or fur-
 7 niture that is soiled. Dirtied painted wainscots
 8 may be cleaned by wetting a sponge in the li-
 9 quor; then dipping it in a little fine clean sand,
 10 and afterwards rubbing the wainscot with it.
 11 [American Farmer.]

PERKIN'S STEAM ENGINE IMPROVEMENT.

A bill has passed the Legislature of New-Jer-
 1 sey to extend a Steam Mill charter, with a view
 2 that the company may avail themselves of the
 3 late improvement of Mr. PERKINS in the steam
 4 engine.

A letter has recently been published, said to
 1 have been written in London, containing the
 2 following remarks:—"Mr. P. is still in London
 3 engaged with his new steam idea.—They think
 4 here it will not answer.—PERKINS, however, I
 5 understand, still entertains hopes." We have
 6 just conversed with a gentleman very recently
 7 from England, who is intimately acquainted
 8 with, and frequently visited Mr. P. who assures
 9 us, that he has perfect confidence in the success
 10 of his improvement; and has received a note
 11 from the most scientific man in the kingdom
 12 who has carefully examined it, expressive of
 13 his approbation of the principle, and confidence
 14 of its success in saving of fuel.—Our informant
 15 was assured that Mr. P. had already contracted
 16 with a person for the use of his engine, when
 17 completed, for a branch of the Gauges, for
 18 20,000. sterling. The amount of the saving of
 19 fuel had not been ascertained, but the most in-
 20 credulous were satisfied that it would exceed
 21 one half, while others believed it would be
 22 three quarters. Mr. P. was very happy and
 23 well-satisfied with his prospects, and the atten-
 24 tions which had been paid him by all the science
 25 and rank of the kingdom.—Boston Centinel.

From the Massachusetts Yeoman.
IRRIGATION.

We have in our possession a manuscript principally relating to the subject of Irrigation, from the pen of a practical farmer, whose whole energies are devoted to the cultivation of the soil. It is much too prolix for publication entire, and seems rather to have been designed for a registry of the writer's observations, reflections, and experiments, than for an essay for the press. It contains, however, many remarks which will be interesting, perhaps when it is understood that they proceed from a man who has little intercourse with the world, but confines his attention to the cultivation and improvement of his own small domain. The quaintness of its style may rather induce than discourage the perusal. We give, below, some extracts, and may, perhaps, give others as we have leisure to examine it.

Of what is called manure, the quantity in running water is small, although raised to a large swell or freshet. Consequently a large quantity of water is requisite to be drifted over grass land, before a sufficient quantity of manure will be lodged among the roots, or be imbibed.

Many pieces of mowed ground, called swails, are drenched often, by large quantities of water, and where the quantity is ample and the operation frequent, the husbandman receives large crops without any occasion for manuring. Those who have applied water without manure, and water with manure, may object to the efficacy of water alone, excepting where the soil is deep and moist. In answer to this—hard or even dry land may be kept moist, if the stream be sizeable and durable, especially till a luxuriant growth shall help to defend from drought; and, if the soil be good, two feet deep, or four, the nutriment for which I plead, carried in water, is what constitutes said soil; and, if water deposits such masses so congenial to grass, why may it not nourish where artificially directed, and in process of time, make a soil having the same constituent agents? Exclude the water from deep and moist soil but two years, and there will be but half a usual crop—direct it upon hard, shallow, and dry ground, (having water in plenty and judiciously managed,) and there will be double in the same time. This manifests that the crop depends more upon water than upon good soil.

Now for the signal contrast between him that has three tons of hay per acre, by water, and him that has it by water with manure. The former observes the natural or accidental washings—that the most productive spot of swail receives—the quantity of water—length of time and number of times in a year—and that it was showered when the water was overflowing its banks, carrying more than ordinary manure. To imitate this process, he digs his trench or canal twice as capacious as a man inexperienced would judge necessary to take the whole brook at its greatest swell—observing that, when there is a copious flood, it is richly impregnated, and should be all applied. At such seasons if the natural banks are too near or too shallow to contain the whole fluid, it finds room enough on the sides; and his canal has, generally, less fall or descent than the natural channel, and will not take so much water in the same time and space. He shovels away the snow when an early flood requires his help, and improves all high water, through the year, excepting near or at the time

of making hay. When water is turned out of its natural course around a hill or across plain or level land, it is generally to be filtered over sloping ground; and whether sloping or level, he does not spread water over the largest part of the ground within its sweep, at one and the same time; but directs a flood in one place for a short time, then shifts it to another, and so on. His outlets, or places of turning the water out of the canal through the bank, are as broad as his canal, having gates or barriers to shut or open at his option—and the same, or like them, across the canal a little below the outlet; so that when open the other may be shut.

Much more might be added; but it is time to observe the process of him who manures and waters the ground at the same time.

He digs a small trench, takes no water when impregnated with food for plants; but clean, stale water is let on all the ground at the same time, enough to wet the manure.* He has a good crop of hay when his trenches are kept open and well tended; but he grudges digging up such grass as grows in water-courses, and suffers less. He permits Providential bounty to pass by to the ocean, lest he should deviate from ancient and modern good husbandry, or lest he should drown land at a time of much rain, when his ground is too wet for any kind of plants. He drives twenty or thirty loads of manure where he might raise three tons of hay per acre without it, and is one that will not change his husbandry nor his opinion.

* "Pure water forms a meagre diet for plants." *N. E. Farmer*, Vol. 1. p. 190.

From the Bennington (Ver.) Gazette.
SHEEP.

Now is the time to select choice, good Bucks. It is in vain for people to expect that they can have fine wool, without Merino Bucks. Twenty years since our wool was all of the coarse kind; and our manufacturers were ignorant of dressing cloth; and yet, at that time, sheep were considered a profitable stock, and the farmers who have worn their *homespun*, are now most of them rich and independent. Many are the mortifications which they and their children have suffered in consequence of the coarseness of their dress; but the time has now come when every farmer can vie with the prince on his throne, in the texture of his coat, by a proper attention to his flocks.

On this subject, a writer in Pennsylvania says—
"The farmers ought to grow more wool: let them bear in mind that all the wool we grow, we manufacture—that we import and manufacture millions of pounds of raw wool every year, besides the millions of dollars worth of woollen cloths, blankets, &c. &c. which we annually import and consume. The farmer will bear in mind, that Wool is in demand; that the demand is increasing: that it fetches a good price. That the growth is not only a duty they owe their family, but their country: and that, therefore, interest, duty, and patriotism cry aloud to our farmers, 'Grow more wool.' I beg again to recommend the importation and improvement of the breed of sheep.

Cotton Spinning.—The unparalleled rapidity of improvements in the art of Cotton Spinning has of late years, been a subject of astonishment

to the most sanguine: still this beautiful and efficient process is capable of attaining a higher degree of perfection; and as it is the basis of manufacturing which evidently will be of greatest importance to this country, no pains or exertions should be wanting to bring it to the highest state of improvement, and keep us on an equality with our great competitors in England. An improvement has been made by the invention of the present mode of drawing cotton upon general use, i. e. with double heads and rows of rollers, by which he proposes to perform that operation in a more perfect manner, with less labor, on simplified and less expensive machinery, the principles of which he will explain, and put the machines in operation in the manufacturers in Philadelphia and its vicinity who may wish it. Phil. Gaz.

FOR THE NEW ENGLAND FARMER.

Mr. Editor—The following remarks, relative to Farming, Good Husbandry, &c. are at your disposal. You are at liberty to publish them in your useful paper or reject them, as you may think proper.

Farming is an occupation that requires, at least, a common share of talent and understanding in him that follows it, to make it profitable and advantageous. The old idea that he is fit for nothing else will do well enough for a farmer, is now well nigh exploded, and a new era has already commenced with regard to agriculture, one by which, we trust, that art will be delivered from the shackles of tradition. The stale notions of our ancestors which have been handed down from one generation to another. The farmer, in many instances, has long followed in the steps of those who have gone before him—too long has he adhered to the general practice of common course plowing. The old spot, in many instances, has tilled long enough; it is now time to break the fallow ground and make the rough p-smooth, that they may become fertile and ductive.

Agriculture is an art or science that will admit of continued application and constant improvement without being perfected or brought to a close. Let it be pursued without deviation, let every great improvement be made, let experiment be tried, still boundless fields open to our view and it is beyond our sight.

Although perfection may be unattainable, the farmer ought to be making exertions for improvement, and continually seeking out the means in which he can manage his business and vate his farm to the greatest advantage and fit. Economy is a necessary qualification possessed by a farmer, as without it he will be like a ship without a helm, be constantly to be driven upon the sand or dashed on rocks. He may make large calculations, expend much time and money, and in the end obtain nothing great or valuable unless he be economical and frugal. It must be his endeavor to make as great improvements and accomplish much business in as short a time and with the least labor and expense as possible. Every man must be attended to in season, or loss is sustained, for by carelessness and inattention, or neglecting a piece of work too long, double the expense is frequently incurred. Business should always be so arranged that it may not interfere with another, and

cause perplexity and confusion, which otherwise might be avoided.

It would be advisable for the farmer to adopt particular rules and regulations respecting business, the management of family concerns, mode of living, &c. as such rules and regulations, if they be salutary and good, and strictly adhered to, will tend to promote order, despatch in business, and a saving in various ways. He would so make his calculations that his income should exceed his expenditures, that he may annually have a surplus to add to his capital stock. In erecting buildings and fences there should be a particular regard to convenience, utility and taste. The dwelling house should be situated on rising ground, there being in it a regular descent each way, and a free circulation of air, as this will greatly conduce to health and comfort. In front of the house there should be sufficient room for a convenient path, which should be made perfectly level and smooth, and enclosed with a suitable fence. Back of the dwelling should be the garden, and a piece of ground enclosed for fruit trees of various kinds. Wood and chips, and other inconveniences necessarily attached to the house, should not be permitted to remain in a scattering and slovenly manner. If dirt or litter of any kind should necessarily or accidentally be left near the house, it should be immediately cleaned up and taken away.

In the house every thing should be kept neat and clean, and every apartment frequently swept and thoroughly cleansed, not even neglecting the back room gullet. The cellar should not be forgotten or neglected—this too, ought to be kept as clean and as well regulated as any other part of the dwelling.

The barn should be situated not far distant from the house, and on a level spot of ground, if possible, the yard being dishing or lowest in the middle in order to receive the drainings of manure, which, if permitted to run off, might be entirely lost. Every thing about the barn, either within or without, should be well adapted, bearing the impress of neatness and order. The hay and grain, the corn stalks and sheaves, should each be stowed away in their proper place, and in regular order; the mow and fold also being handsomely raked down.

During the season of feeding cattle, much care and attention is necessary. They should be constantly attended by the same hand, as the farmer can be dealt out to better advantage by than by different persons, and the cattle will undoubtedly do much better. The apartments in which the cattle are confined during the night, together with the cribs, should be kept clean and in good order. Scatterings of straw and hay should not be permitted to lie out in the way, and as often as the cattle are the litter should be cleaned up, and every thing properly regulated. Cattle should not be allowed to ramble over the fields or in the highway during the season they are fed from the mow, as much would thereby be lost, not only the article of manure, but also in their keeping, they undoubtedly require more fodder than they would were they kept closely confined in the yard. Water should always be brought into the yard by an aqueduct if possible, as this method of watering cattle in the winter is unquestionably preferable to any other.

In erecting fences, care and attention is ne-

cessary in order to have them durable and lasting. Stone wall is, undoubtedly, the best kind of fence that can be built, where rocks are plenty and of a suitable size, and is, on the whole, probably the cheapest. If a trench be dug in common soils twelve or fifteen inches in depth, and three or four feet in width, and filled even with the top of the ground with small stones and a wall built thereon, it will last an age. Every farm ought to be well fenced, and the farmer should see to it, that his fences are constantly kept in good order; for if they are bad and out of repair, his crops are liable to be destroyed, and his cattle will most certainly become disorderly and troublesome.

Every farmer at the present day has weighty and powerful motives placed before him to induce him to be industrious and enterprising, and to make every exertion in his power to excel in the art of husbandry.

It should be the ambition of the husbandman to make great and valuable improvements on his farm, for thereby he will enhance the value of his property, and merit the applause of those around him.

Almost every farm of any considerable extent, has more or less rough or broken land, which remaining in its natural and unimproved state, is of very little value. Much of this land were it subdued and cultivated, would turn out to be the most valuable part of the farm that contains it, and it only wants the hand of the skillful agriculturist applied to it, to render it productive and profitable. A gentleman within my knowledge, who by the way is an enterprising, practical farmer, a few years since bought a piece of land, the greater part of which was considered to be almost worthless. On one part of it was a large boggy piece of ground, which had been cleared many years, but produced nothing but brush and rubbish, and was thought to be altogether unimprovable. He has completely subdued, and converted it into an excellent piece of mowing land. On the same lot was a small brushy pond of water, this has been drained and is become a beautiful and fertile spot. The same gentleman has near his dwelling a piece of ground, which but a few years ago was literally a quag, but by draining and skillful management, he has caused it to become a valuable piece of ground, producing two crops in a season.

FOR THE NEW ENGLAND FARMER.

Some time since a gentleman of Boston sent a copy of the pamphlet "On the Duties and Dangers of Sepulture," &c. to an eminent physician in Halifax, Nova Scotia, from whose reply the following is an extract.

"Halifax, 20th Oct. 1823.

"I delayed answering your last favour of the 19th September, till I should have had an opportunity to peruse the pamphlet you so kindly sent me; for which I feel much indebted, and tender my most cordial thanks.—I have now given it an attentive reading, and also shown it to some of my medical friends, and feel much pleasure in being authorized to assure you and the author that it has their perfect approbation as well as mine.—It is somewhat remarkable that the very evening before the book arrived, the subject of it had been under discussion at my house. The conversation originated from one of the company's observing that it was an abominable thing to have the most public burying ground op-

posite to Government house, (a fact) and that it was his opinion it ought to be abandoned, and as soon as possible appropriated to some public use. Another of the party expressed a degree of horror at the idea of converting it to any other purpose than that for which it was originally intended. Answered that so far from entertaining the delicate scruples of my friends, I was so thoroughly convinced of the danger as well as absurdity of having grave-yards within the precincts of any town, that, notwithstanding I had numerous relations buried in the ground under consideration, I would without hesitation give my vote for removing every monument erected over them, completely covering them over, planting ornamental trees on the borders of the spot, and establishing it as an open square for a public walk, but not to be encroached on for any other purpose.—The opinion of the majority was in my favor."

From the Boston Medical Intelligencer.

HABIT.

Dr. Plott, in his history of Staffordshire, tells us of an idiot that lived within the sound of a clock, who was always amusing himself when it struck. The clock being spoiled, the idiot continued to strike and count the time without it, in the same manner he did before.

A lady of this city has contracted the habit of counting the panes of glass in a house, the moment she casts her eye upon the window. She has repeatedly assured her friends it is impossible to cure herself of the habit, and that the sense of weariness and pain from associating the number of panes with the idea of a house or window, is a hundred times worse than the labor of superintending the concerns of her family.

A boy in Vermont, accustomed to working alone, was so prone to whistling, that as soon as he was by himself, he unconsciously commenced. When asleep, the muscles of the mouth, chest, and lungs were so completely concatenated in this association, that he whistled with astonishing shrillness. A pale countenance, loss of appetite, and almost total prostration of strength, convinced his mother it would end in death, if not speedily overcome; which was accomplished by placing him in the society of another boy, who had orders to give him a blow as often as he began to whistle.

An attorney insensibly contracted a habit of numbering his steps, when walking, and when in his office, of thinking how many paces distant were certain places in the neighborhood. He found it nearly impossible to meditate on any other subject. He fancied a cure was effected by walking over the stream, on a pole, where he was in imminent danger of being drowned.

A trunk maker, in the country, could never refrain from biting his nails, at a moment of leisure. In 1816, every appearance of a nail on the left fingers and right thumb was obliterated.

A child, in New Hampshire, who was usually seated in the meeting house, on the Sabbath, opposite an old gentleman who labored under chorea sancti viti, contracted the habit of imitating his distorted features, to such a degree, that his face was continually in a grimace.—The child was cured by working at needle work, before a mirror.

A pious woman in the eastern section of New

Hampshire, who drew large quantities of water from a deep well, with a pole, was repeatedly observed, at her evening devotions, before the bible, unconsciously moving her arm all the while, as in drawing the bucket from the well.

Mr. C. who committed suicide two years since, was constantly pinching his left cheek if his left hand was not otherwise employed. The consequence was, a hard callus, of the size of a dollar, formed over the buccinator muscle, that materially injured his speech; he could not blow out a candle, nor bring his lips to the blowing hole of a flute, on which he was formerly a good player.

November.—Now begin your preparations for winter. See that your windows are repaired, loose boards and shingles fastened; your carts, ploughs, hoes, &c. safely sheltered. School now demands particular attention. Be cautious whom you obtain for a teacher. No man should be employed without a strict examination. Beside sustaining a fair moral character, it would be desirable if every teacher of children were a christian: almost every thing, in future life, depends upon early impressions and habits. Some teachers are certainly worse than none—they are grossly ignorant of what they attempt to teach, having no regard for the mental or moral improvement of their pupils. Be not so anxious for a cheap master, as for a good one.—*Christian Almanack.*

Fifty millions of dollars, (says a writer) it is calculated, will be spent this year in the United States for ardent spirits—that will be about \$5 for each individual on the average; while our national tax is about \$2! "But," says a writer, "Fifty millions of dollars lost is a trifle, a point of vanity compared with the moral influence of intemperance. This immense sum has poured down the throats of about 4,000,000 of men 75,000,000 gallons of liquid fire. A quantity sufficient to supply a constant stream of 3000 gallons an hour—a quantity which, if collected, and put into a reservoir, would form a small ocean, on whose bosom might be anchored a line of war ship half a mile in length, or, if gathered into a canal, would fill one four feet deep, fourteen feet wide, and thirty miles long.—*Connecticut Herald.*

From the American Farmer.

"Ardent spirits are not only eminently destructive to the body, but are the most powerful incentives to vice of every kind; drunkenness engenders all other crimes. Does the robber pause in his trade? Does the murderer hesitate? They are presently wound up at the gin shop. Has the seducer tried his arts in vain? The brothel is more indebted to this source, than to all the other lures to seduction."—*From Hints for the Preservation of Health.*—*Callow,* 1813, 12 mo. p. 2.

Good Liquid Blacking for Boots & Shoes.—Mix a quarter of a pound of ivory black with a table spoonful of sweet oil, dissolve a penny-worth of copperas, and 3 table spoonfuls of molasses, in a quart of vinegar, afterwards adding two penny-worth of vitrol, then mixing the whole well together, it forms a good liquid blacking for shoes, &c.

NEW ENGLAND FARMER.

SATURDAY, NOVEMBER 22, 1823.

BEES.

Mr. Huish a celebrated writer on bees, Fellow of the University of Arts and Sciences of Göttingen, &c. &c. says that "in southern countries the aspect of the beehouse should always be to the east, to give the bees the first light of dawn. In the northern countries, the aspect should be between south and east, to enjoy the morning dawn, under a shelter from the north winds. The hives should always stand upon a right line, in a single row; that rows one above the other do well, but seldom when double on the same shelf—as they are more exposed to robbery from each other. The bee in his flight from the hive, generally takes an elevation of 45 degrees from the horizon, therefore, the hives should stand low, say two feet from the ground. This elevation will guard the bees against the moisture of the ground, the toads, mice, ants, &c. and prevent their gaining such an ascent in their flight, when they swarm, as to prevent their lighting, and thus occasion their loss to the proprietor. The board on which they stand, should be carefully secured against warping, as the wasps, &c. will rob the hives at such openings, under the bottoms of the hives, and every shrub, plant or weed should be cleared away from the apiary, that can obstruct the flight of the bees, or give the mouse, the ant, &c. access to the hive; and great cleanliness should be observed in and about the apiary generally. The neighbourhood of large towns, and large rivers are unfavourable situations for bees; the first on account of the smoke, the swallows, particularly the chimney swallows, and the last from being exposed in their flights to high winds."

Mr. Deane says, "A bee house should be situated at a good distance from places where cattle are kept, especially from hog sties, hen and dove houses, and remote from the filth of dung hills. It should be defended from high winds on all sides, so far as may be consistently with admitting the heat of the sun. The house should be open to the South, or South West, and the back side should be very tight; with a tight roof projecting, that driving rains may not injure the bees.—If snow lodges on or about the house it should be brushed off without delay. The bench on which the hive stands should be a little canting outwards, that if wet should fall on it, it may run off without entering the hives. All seams are to be stopped, which would admit insects, from which the house is often to be brushed.

"If the house should be in danger of being too hot, when thus inclosed, it may be occasionally shaded with boughs of trees. As winter approaches all the seams of the house are plastered with clay. In very cold climates the house should be filled with straw, to keep the bees warm, watching against mice, and removing the straw in the spring."

A writer in Rees's Cyclopaedia observes that "it may be necessary to feed bees towards the close of autumn, in the winter, or in the spring, when they have consumed their winter stock. This should be done, especially in cloudy, misty weather, when they go abroad but little, and when several days of bad weather immediately follow their swarming. Mr. Thorley directs that no hive be kept that does not weigh twenty pounds; and that the supply be given in quantities of honey, which is their proper food, not less than a pound and a half or two pounds at a time. The honey should be first diluted with water, or small beer and then poured into an empty comb. In the evening when the bees are quiet, the hive should be gently raised on one side, and

the comb put under it; the contents of which will be conveyed away the next day into their several magazines."

Mr. Huish directs not to feed bees profusely, but give them about two pounds a month, and to administer their food either in the morning early before the bees leave the hive, or in the evening after sunset when the entrance of the hive need not be closed, after given the honey, but the vessel containing it should be removed before the next morning to prevent robbery. The feeding should not be delayed till the old store is exhausted, lest the bees become feeble, and if the survive will be less able to labour the next season. He says that neither sugar nor clear honey should be given. Sugar is improper food, and often exposes bees to the dysentery, and recommends that honey be mixed with good old white wine, in the proportion of six pounds of honey to one of wine; it should then be placed on a slow fire, and stirred till the honey is dissolved; then let it be poured out into a jar or other vessel for use. It has been advised to add a little salt to their food, especially when they are threatened with dysentery.

FINE ROOTS.

John Prince, Esq. of Roxbury, has sent us some specimens of his root crops of the present season, which cannot fail to impress a favorable idea of the improved system of husbandry pursued by that gentleman, and some other cultivators in the neighbourhood of Boston who have "turned over a new leaf" in American farming. We have received from Mr. Prince a root of *Sugar Beet*, raised by him, in field cultivation, of the *true kind*, the seed imported by Mr. Prince from Paris. This sort is sometimes distinguished by the name of the *Buonaparte Beet*, being the same kind, which Buonaparte employed in the manufacture of sugar. It is one of the varieties of the *Beta vulgaris*, or common garden beet. The skin is of a reddish colour, and the flesh white. It contains more sugar, according to experiments of European chemists than any other plant cultivated in Europe, and exceeds what is called the *red beet*, or *blood beet*, in that respect. It undoubtedly contains nourishment in proportion to its saccharine matter.

We have likewise received from Mr. Prince a root of the *true Mangel Wurtzel*, the seed imported from Europe. He has raised seed of both kinds (the *Mangel Wurtzel* and *Sugar Beet*) this year; has disposed of all the seed of the *Sugar Beet*, but has 20 or 30 lbs. of the *Mangel Wurtzel* seed to spare. That gentleman observes that he intends to raise largely of the seed next season, having selected a quantity of fine roots for the purpose, and adds, "I think most highly of both sorts of these roots for all kinds of stock.—They are raised at very much less expense than carrots, and I kept them till June the past season in fine order." Mr. Prince is not a mere speculative farmer, who farms in his closet, but practices himself what he recommends to others, and gives the public the results of his own experience. The seeds which he raises are not liable to be adulterated by the mixture of sorts which should be distinct, as he sets his seed plants which might be deteriorated in that way, at such distance from each other, as to preclude any injury from that cause."

Mr. Prince has likewise sent us a common English turnip, which after being closely trimmed, and quite dry, weighs 8 1-2 lbs. This together with the specimens of the *Sugar Beet*, and the *Mangel Wurtzel* may be seen at the office of the New England Farmer.

* See remarks on raising and collecting seeds, N. E. Farmer, vol. 1. page 405.

The Claremont Spectator, after quoting from the precursor Spy, the account of Dr. Fiske's turnips, says, "An English Turnip raised the past season, in the garden of Hon. Samuel Fiske, of this village, *beats the best of all hollow*!—weighing 13 pounds, and measuring inches in circumference, and in thickness 7 inches—outer edge being of nearly equal thickness with the core."

NE PLUS ULTRA.

sac Bassett, jr. has left at our office, for the inspection of the curious, an English Turnip, which exceeds any we have seen or heard of; measuring 3 ¹/₂ inches in circumference; largest diameter 14 inches; thickness 7 inches—and weighing within the top, 20 POUNDS, and 2 OUNCES.—*Worcester Spy.*

FOREIGN.

Spanish Affairs.—The King of Spain immediately on arrival at the French head quarters, issued a declaration of "fire and fury" in which he complains "the most criminal treason, the most disgraceful meanness, the most horrible offences against my royal person," &c. and says, "the tyrannical constitution," "a code null in its origin, illegal in its formation, unjust in its principle;" and "replaced upon the throne of St. Ferdinand, by the just and wise hand of Providence, as well as by the generous efforts of my allies and the valiant enterprise of my cousin, Duke d'Angoulême and his brave army, desirous of applying a remedy to the most pressing necessities of the people, &c. I have authorised the following Decree." "ART. 1. All the acts of the government called constitutional (of whatever kind and description they may be,) a system which oppress my people from the 1st of March, 1820, until the 21st of October, 1823, are declared null and void, declaring, as I now declare, that during the whole of that period I have been deprived of my liberty, obliged to sanction laws and ordinances, decrees, and regulations, which the government framed and executed against my will. "ART. 2. I approve of every thing which has been decreed and ordered by the Provisional Junta Government, and by the Regency, the one created at Oporto, April 9, the other May 26, in the present year, during meanwhile, until sufficiently informed as to the wishes of my people, I may be able to bestow those laws, and adopt those measures, which will be best calculated to secure their real prosperity and welfare, the constant object of all my wishes.

"My decree, however, is modified by a Proclamation, (it not a forgery as some have suspected) which appeared in the Gibraltar Chronicle of the 4th of Oct. in which he promises on the faith of his royal word, that, if necessary, the existing political institutions, which he will adopt a government which shall secure the freedom and prosperity of the nation, and that his subjects shall not be molested for their political principles or conduct—recognizes national debts and obligations contracted under the present system, introduces much other conciliatory matter, which his royal promise can be relied on, may lighten the hearts and soften the fifters of his Majesty's happy, contented and loyal subjects.

Northern Expedition.—Capt. Parry, commander of the Discovery ships which sailed in quest of a North West passage, arrived at the Admiralty on the 18th of October. He had not been able to effect the North West passage. In 1821, the expedition explored Repulse Bay, Sir Thomas Roe's Welcome, Middleton's Frozen Bay, and that neighbourhood, and finding no passage to the northward and westward, wintered in the South Bay of an Island called Winter Island, in lat. 68° 30' N. and long. 81° 50' W.

In 1822, they pursued their attempt to the northward, and examined all the inlets towards the west, they arrived at a Strait, which separates the North coast of America from what Capt. Parry considers to be a cluster of Islands extending northward towards the pole of his former voyage.

The great object of ascertaining the northern limit of the continent being thus accomplished, Capt. Parry departed two degrees to the westward, with considerable expectation of final success; but in a narrower part of the strait, they found the ice fixed in that peculiar manner which indicates that it is perpetual, and not subject to any season, or under any circumstances. The expedition was therefore, in lat. 69° 30', long. 81° 50'.

In the summer of this year, finding the ice still fixed to the shores, in such a manner as precluded all hopes of any further progress in the neighbourhood in which he was, Capt. Parry thought it advisable to give up the attempt and return to England.

DOMESTIC.

Directions for curing the Grass for Ladies' Hats.—This grass, known by the name of "Spear Grass," was cut on the 13th of June, when in a green state, the blow just dropping off—put in scalding water five minutes; laid in the sun one day; scalded again in the same manner; laid in the sun and dew till it becomes perfectly dry, time about one week, taking care that no rain falls upon it; then trim it; for in this instance only the top joint was used; scald in it pearl ash water and soap suds five minutes; then smoked in brimstone till nearly dry; taken out and laid in the sun till perfectly dry, when it is fit for use.—*Boston Cent.*

Counterfeit dollars, Look Out!—It is believed that large quantities of Spanish Milled Dollars, in imitation of Ferdinand VII, 1823, have been manufactured in Europe, and introduced into the U. S. through the late emigrants to Canada. The Montreal papers say they may easily be detected by sounding them on a table.

We understand a gentleman from Rockingham a few days ago exchanged paper for \$300, and gave a premium to a stranger passing through town, and to late discovered they were all base coin, of the above description.—*Keene paper.*

Counterfeit Five Dollar Bills of the Keene Bank, new plate, are in circulation. Several have been presented to a Broker's office, in this city, the present week.—*N. Y. Com. Adv.*

New Inventions and discoveries.—A machine has been submitted to the French Government, for throwing water into an enemy's ship during action, so as to prevent the vessel being worked. This machine, which can be worked by ten men, will throw, at every stroke, upwards of two tons of water a distance of more than forty yards, if required, and thereby prevent the possibility of working the opposing ship.—*N. Y. Eve. Post.*

Connecticut yet.—A hog 26 months old, owned and fattened by Mr. Thomas Way, of New-London—weighing twelve hundred and fifty lbs.—girth six feet four inches, and length nine feet, was on Monday last shipped for New-Orleans.—*New-London Advocate.*

At the Schohara Show, N. Y. a married woman presented three infant daughters of one birth. As no premium had been offered for this most valuable product, the batchelors present agreed to present the prolific lady with \$5 each, making in the whole a very handsome purse.

Wheat Market in Troy.—A Troy paper of the 28th ult. informs that "during the last week our millers have purchased rising 5000 bushels of wheat at 10s. 8d. to 11s.

The State Prison of Vermont is stated to have yielded a net profit to the State, after defraying expenses, of from 800 to 1000 dollars the past year.

A pig was raised by Mr. William Gardner, of Newport, and killed on Monday last, (when he was eight months and three days old,) which weighed, exclusive of rough fat, 355 pounds. Beat it who can?—*Repub.*

NEW ENGLAND FARMER.

FOR sale by WELLS & LILLY, No. 98, Court St. the New England Farmer, or Geographical Dictionary, containing a compendious account of the Ways and Methods in which the important art of Husbandry, in all its various branches is, or may be pursued to the greatest advantage in this country. By SAMUEL DEANE, D. D. &c. Third edition, corrected, improved, greatly enlarged, and adapted to the present state of Agriculture. Price, neatly bound and lettered, Two Dollars. November 1.

FARMER'S ALMANAC, FOR 1824.

FOR sale at this Office, the Farmer's Almanac for 1824. Nov. 24.

JACK FOR SALE.

BARBAROSSA, a Jack, bred by the subscriber, from a large Spanish Jennet, and sired by an imported Maltese Jack of the pure *Omagra* stock, is offered for sale. He is now two years and four months old, measures 14, and will, when at his full growth, undoubtedly exceed 15 hands in height—uniting the bone and power of the large Spanish breed, with the spirit, activity and vigor of the Maltese. At the late exhibition at Brighton, he was pronounced, by several gentlemen of respectability, who have examined this species of stock in Spain, the Islands in the Mediterranean, and in South America, to be superior to any they ever saw.

BARBAROSSA is perfectly docile and kind, was kept with a Filly immediately after weaning, and has propensities, seldom found in imported Jacks, which must enhance his value in the estimation of those accustomed to breeding mules. A full warranty of his powers will accompany the bill of sale—and the subscriber has no hesitation in asserting that he is equal to the celebrated Jack, *Compound*, bred by Gen. Washington; (being of the same grade) and that he is superior to any now in the United States or that can be imported.

If not applied for speedily he will be shipped to the Island of Cuba, where a much higher price can be obtained than is now asked. S. W. POMEROY.

Brighton, Nov. 21, 1823.

FOR THE NEW ENGLAND FARMER.

On the necessity of destroying some animals and preserving others for the use of man.

Whatever of earth is form'd to earth returns,
Or takes the shape of matter decompos'd
To pristine particles unorganiz'd,
Which constitute the principles of things—
Plants, animals, and all the mighty mass
Which forms the Universe are shifting still
In ceaseless change. All but the *soul of man*,
That particle divine will be the same
Amid the crash of worlds and wreck of matter.
Hence, great the distance, which exists between
The brutes, which perish, and immortal man.
The lower order of created things
Were made for man, subservient to his will,
Plac'd under him by that ALMIGHTY POWER,
Whose word omniific gave creature birth.
The brute inhabitants of earth, sea, air,
Though subject all to Man's supreme control,
Still claim the rights contain'd in Mercy's code—
And he who gives them needless pain deserves
To feel the pain his cruelty inflicts.
But still the noxious and the useless tribes
Of animals are rightly doom'd to slaughter;
And some must bleed to pay the just demands
Of man who nourish'd them, without whose care
And toil incessant, they had never been.
Should he not kill (as erst Pythagoras
Taught his disciples, and as Indian Bramins
Vainly contend) the fierce and ravenous brutes
Would soon make earth a desert fill'd with nought
But beasts and birds of prey—should not his care
Improve his growing stock, their kinds would fail:
Man then on roots and acorns must subsist,
And dwell in caves and hollow trees forlorn,
Quite destitute of every solace dear,
Connubial bliss, the ties of friendship—all
Which gives to life its polish and its zest.

MISCELLANY.

From the Connecticut Mirror.

MR. PRINTER—I have been absent on a voyage to sea, for about six months; when I left home, my daughters, four young women, from fifteen to twenty-two, were plain dressed, neat, industrious girls, who weekly, in rotation, managed domestic affairs, and were a great relief to their mother. My weekly superintending the business of the family, every thing went on in perfect order and regularity; we had very little occasion for hired help, except on washing days. When I left home, I considered my family as happy and economical as I could desire. The girls would anticipate my wishes, and those of their mother; and I may say without vanity, our house was kept as neat and in as good order as any other. I confess I took a pride in the neatness and simplicity of my daughters' dress, especially in the manner in which they dressed their heads. But on my return, I was not only astonished, but absolutely mortified at the change which had taken place under my roof! On entering the door, I was met by a servant girl, with a bowl, containing a rag and brick dust, to scour the knocker, (for it seems in my absence they had hired a maid to do that which they used to do themselves.) I concluded it was some hired woman for the day, and passed on. On entering the room, I was as-

tonished, at beholding four young ladies, seated round the fire, with each a novel in her hand, and heads so be-curl'd and be-frizzled, with large flaunting ribbons "nailed on the fore top," that I verily thought I had made a mistake, and got into the wrong house. I made a respectful bow, begged pardon and hastily withdrew. In the entry I met my wife; she looked very much (good old soul) as she did when I left home. I asked her what company was in the other room. I knew it could not be what they called a *bee*, as neither of them had any work, and concluded it must be a *reading Society*, as I had understood such societies existed. My wife laughed very heartily, and said she was not aware that any company was there except our own daughters. I replied she must be mistaken, for when I entered the room I did not know either of them; and I was sure they were not the same faces I left at home. Here I was called out for a moment to see about my things the drayman had just drove up to the door. My wife passed into the room where the girls were, when they all rose and exclaimed at once, what is the matter with Papa? He entered the room, started, made an awkward bow, and suddenly withdrew, as if he did not know us! We thought he was crazy, and were so confounded ourselves, that we could not speak to him! On my wife's stating to them that I was perfectly well, they were somewhat pacified, though they felt hurt, and began to cry. At this instant I returned, they all spoke to me and were rejoiced to see me; and by their voices I knew I was with my own family. The incident gave us all much pain for the moment; but we soon recovered from the panic, and I am now happy with my wife and children around me. Though I must say, for the life on me, I did not at first know my own children, so much was their original beauty obscured by Curls and Ribbons. I rallied the girls on their strange appearance, but they repelled every argument, by saying it was now all the fashion. Their good natured mother interposed in the girls' behalf, and was going to justify their ridiculous deformity on the score of fashion—when, not being exactly prepared for a long discourse, "short blessings and long puddings," as we sailors say, I deemed it necessary to "buff and bear away," remarking by way of "stern chaser," that I hoped the fashion would not again change so as to create a similar embarrassment on my return from the next voyage. I then placed my ship's papers in the draw of the table under the looking glass, and requested my eldest daughter to get me some dinner. She said as soon as she had adjusted her curls, (which had become a little discomposed by the previous scene) she would direct the *servant maid* to prepare it. I left the room while dinner was preparing. But whether through impatience at the strange looks of my daughters, or from being sharp set for my dinner, I cannot say, but it appeared to me they were a long time getting it ready. I returned, and after taking a *welcome glass*, I thought I would kill the time, which hung heavy before dinner, by adjusting my papers—when to my great surprise, I found two of the most valuable papers missing. I inquired what had become of them? At length I found, while I was out the girls had taken them to do up their curls. After making some ado at the loss of my papers, of which I had no copies, they untwisted them

from their pates matted up like prepared wadding for a fowling piece! The girls were mortified and was angry; I sat down to my dinner, with loss of appetite, severely cursing curls and their wanton destruction of valuable papers.

BOB STRAIGHT HAIR.

Words in Languages.—By a reckoning made for the best dictionary for each of the following languages there are about 20,000 words the Spanish, 22,000 in the English, 25,000 the Latin, 30,000 in the French, 45,000 the Italian, 50,000 in the Greek, and 80,000 the German.

Of the 22,000 words in the English language there are about 15,000 that a man understands who is before master of Latin, French and Italian, the other 7,000 are probably old English.—*Spence's Anecdotes.*

White Teeth.—The famous Saunderson, though completely blind and who occupied, so distinguished a manner the chair of mathematics in the University of Cambridge, being one day in a large company, remarked of lady who had left the room, but whom he had never before met, nor even heard of, that she had very white teeth. The company were extremely anxious to learn how he had discovered this; for it happened to be true. "I have a reason," said the professor, "to believe that I am a fool, and I can think of no other motive for her laughing incessantly, as she did for whole hour together.

Mourning Dresses.—A writer in the *Past Recorder*, condemns the practice of wearing mourning at funerals as unnecessary, because by no means indicative of true grief, and as being an oppressive burthen to the poor. He recently deviated from this custom in the case of deceased individual of his family, and transmitted 10 dollars to the American Education Society, as a part of the sum saved.

Effects of Gambling.—Henry Brewer, a man of education, was arraigned lately in New York before the Court of Sessions, charged with having forged endorsements on two notes amounting to about \$1500. To which he pleaded guilty, and was sentenced to 7 years imprisonment for each forgery in the State Prison. He was a foreigner, had a family consisting of wife, three children and his wife's sister, all in a strange land. The prisoner had been led to the commission of these crimes by the practice of gambling. Having received from abroad a considerable sum of money, he undertook to try his fortune at gambling, and in one night lost upwards of \$500. After this, in order to replenish his pockets, he committed the above forgery, probably with the hope of regaining his lost money.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within *sixty days* from the time of subscribing will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

Farmers and Gardeners Remembrancer.

[BY THE EDITOR.]

FODDERING CATTLE.

[Concluded from page 130.]

It is of very great importance that your barn be provided with pure and wholesome water, especially if the winter food of your cattle consists chiefly, or altogether of hay, straw, or other dry food. It has been ascertained that a bullock, who has water at command will drink of it eight times a day.* Dr. Anderson says, in substance, that particular attention should be paid, not only that cattle have water in plenty, but that it is of a good quality and that he knew a man, who became very rich by being great in such matters: or, in other words, by attending carefully, to things, which mankind in general consider of too little consequence to command such attention. This man always made it a point to see that his cattle, particularly his calves, should have a constant supply of pure water, and he would not suffer any animal to put a foot into it, or even let it be heated by their breath. Cattle, which are obliged to wander away to some distance from the yard for water, through deep snows, and slippery paths, exposed to be harassed by dogs, and gored by each other, or by neighboring cattle suffer more than is generally imagined. It is this all, rather than adventure on such a pilgrimage, they generally stay about the barn, and loiter along the highway, eating snow on their bellies, which chills them, causes them to have the horn distemper, (a disease brought on by poor keeping) and other injuries then and there does (as the lawyers would phrase it) against the peace and dignity of their owner. It likewise loses a great part of their manure, as well as their thrift; and you must either let somebody, or go yourself, and escort your cattle to water, or you must leave your barn doors down, or gate open, that the poor animals may wait on themselves to their watering place. Then, in addition to the inconveniences, losses above mentioned, your yard is thronged with your neighbors' colts, and other half-bred ill bred quadrupeds, who pay no regard to the rights of *meum* and *tuum*, but steal all the order they can lay their mouths on. Then observe the said four footed plunderers to the barn; and thence cometh lawsuits, quarrelling with your neighbors, poverty, profane language, and other evils natural and moral, too numerous to recapitulation. Therefore, Mr. Cultivator, instead of taking your cattle to water, please to lead water to your cattle, yea, even in a tin-can, an egg-shell, or the crown of your hat, if you can find nothing bigger or better, or we will put you down a *bad husbandman!*

We have heretofore, in a number of instances, recommended the use of roots for feeding and watering cattle, &c. But as the majority of the England farmers do not raise any roots, but the potatoe, in any considerable quantity, we shall here mention some uses to which this very important root may be applied, as for horses, neat cattle, sheep, &c.

End of Agriculture.

POTATOES FOR COWS, AND OTHER NEAT CATTLE.—In Mr. Arthur Young's Annals of Agriculture, vol. xv. is a detailed account of potatoes being used for feeding cows, together with cut straw, which concludes as follows:

"The result of these experiments was that potatoes occasioned the milk at first to diminish, [in cows which have not been used to them,] which may be supposed to arise from the change of food, for it required nearly eight days to accustom the beast to that food, which afterwards augmented their milk about a quart. I also made some observations on the quality of the milk; but it will take up too much time to give my observations on that head in detail. It will be sufficient to observe that the first day, the milk appeared to have less cream, and gave about one seventh less butter than before, and kept in this state about five or six days; after which the milk became thicker, and the cream upon it was in greater quantity. Without becoming yellow, the butter was less white, and many people, who tasted of it thought it more pleasant, but that difference was not apparent to me." The quantity given to those cows, was thirty pounds raw potatoes, and twelve pounds of cut straw to each *per diem*.*

Mr. Marshall, an eminent English agriculturist says, "Potatoes are more nutritious; and in the opinion of those, who have used them, fat cattle much quicker than either turnips or cabbages, and if properly laid up, are a food, which may be continued without inconvenience, until the cattle are finished or the grass has acquired the requisite growth for finishing them in the field."

POTATOES FOR HORSES.—A correspondent of Mr. Young [see Young's Annals, vol. i. page 21.] says, "I had a peck of potatoes, boiled every day, after dinner was cooked in my kitchen, and given to my saddle horses, a quarter of a peck each daily, on which they did their work well as long as they lasted, that is upwards of two months, instead of oats; only a trifling quantity of which were now and then given. If they were roasted on kilns, as I understand is the practice in some parts of England, and mixed with ground oats, it would, I imagine, be a great saving in oats and a more hearty food."

Another correspondent of Mr. Young [see Young's Annals, vol. i. p. 235.] says, "Not having any potatoes of my own, I bought some of a neighbor, to try them in horse feeding, and from the result prefer them to carrots. They were given raw, but washed, to saddle horses, each having a peck a day, and no oats whatever.—The horses were worked moderately, the same

as on oats, did their work well and were in good order. At first they scoured, but it soon went off, and the potatoes did no more than keep their bodies gently open."

Another writer in the same work affirms that potatoes are far superior to turnips, in feeding, to the amount of one third, both being used in equal time. I never had horses in so good condition as when fed upon potatoes. They are a certain remedy for a horse with swollen legs, or out of condition in other cases, and disorders inwardly, one peck a day. They are accounted good for hunters, giving them the day after they have had a severe run, eight or ten large potatoes. Likewise a writer in the 16th volume of Young's Annals, states, in substance, that a gentleman feeds his horses in the following manner. Half a bushel of boiled potatoes is mixed with a bushel of chaff, (and more if it abounds;) the roots are boiled in a basket, which is let in and drawn out by a pulley. One woman washes and boils 25 bushels a day. With this food horses have no oats. He has men that keep horses at work for him, who buy potatoes in preference to oats. The old horses, that used to go down [lose flesh] in winter, do better on potatoes than even in summer.

POTATOES FOR SHEEP.—Gen. Murray uses potatoes for fattening sheep, as well as for lean stock. He has now 196 fat weathers, that eat very near 14 bushels of potatoes and 100 weight of hay *per diem*: it may be reckoned 14 bushels for 200 sheep. If they have as many potatoes as they will eat, they do not require more than half a pound of hay each *per diem*.—Young's Annals, vol. ii. p. 235.

It will be proper in feeding cattle with potatoes, or other roots to give them but a small quantity at first, increasing it by degrees as they become accustomed to that sort of food. It will be better to give a little every day than a large mess, once in three or four days or a week.

Mr. Deane observed that "When a farmer thinks that he has too much stock for his fodder as will sometimes be the case, it is not best to pinch them in their allowance as much in the fore part of winter as in the latter part. For the cattle are more liable to be pinched with cold, in December and January, than afterwards. And no man knows how favorable the latter part of winter may be. Advantage also may be made of browsing in the latter part more than in the fore part of winter, as the buds then begin to swell and the twigs have more sap in them than before."

From the Massachusetts Yeoman.

IRRIGATION.

Further Extracts, by the Editor, from the Manuscript of a practical Farmer.

I have irrigated hard land seven years—and soft, four years. The hard has nearly doubled in crop, once in every three years—the soft in two. If I had been supplied with a plenty of water, I cannot doubt I should have realized twice the quantity of the hard land's crop in two years; but at the time when most needed, my brook was generally almost dry.

* * * * *

* It may be well, however, to state in this place that the Farmer's Assistant is opposed to using potatoes for the purpose of feeding milch cows. That writer says, "We never should advise to feed milch cows with potatoes, either boiled or raw; as we have frequently known cows to be greatly lessened in their quantity of milk, by being fed on this root." It is probable, however, that in the instances to which the Farmer's Assistant alludes, the cows were not fed with potatoes long enough to become accustomed to them. Mr. Young says that potatoes caused the milk at first to diminish, but after eight days its quantity was increased.

He that begins wrong need not expect to end well. I have informed some people that at the harvest I reap across and bind returning, and shock all before quitting work. This has been imitated and attended with considerable loss, occasioned by *beginning wrong*. According to tradition, or custom, they enclosed large quantities in long bands, drawn strenuously close by a severe pull, excluding the circulation of air from the enclosed grain. They found that this husbandry would not answer—monly straw and musty grain was the consequence. My sheaves are small, and bands so loose that those who have not left their *strenuous pull*, judge it would all spill out.—Now he that begins wrong to irrigate, finds the land will not produce well without manure. In one case, the sheaves are too large—in the other, the *trenches are too small*.

* * * * *

We need not much fear drifting too much water on either dry or wet land.—But, as some farmers must wait till the dew is gone before they will allow hay to be opened, so they must wait till the flood is gone before they will have the water.

* * * * *

Water should *pass over*, and not *remain on*, irrigated land. This I find to be essentially necessary, both for soft and hard meadow. Where soft meadows have a narrow outlet, it often happens that half or a whole acre, according to its strait, is ponded near the outlet, in time of a flood. On this, we may suppose more sediment is deposited than on the oxbow bend. Yet here grass will not be so large, nor so good as on the bend. Farmers will generally recognize this.

From the Portsmouth (N. H.) Journal.

ROCKINGHAM AGRICULTURAL SOCIETY.

The Committee appointed to examine the claims for premiums upon Crops—report:

That they recommend premiums to be awarded as follows, viz:—

First premium on Wheat \$8 to Mr. John Gordon of Exeter. The quantity was 39 bushels and one peck upon one acre and 36 rods of land.

First premium on Corn, \$12 to Thomas Jenness, Esq. of Deerfield. The quantity was 100 bushels and nine quarts upon one acre of land.

Second premium on Corn, \$8 to Mr. John Gordon, of Exeter. The quantity was 78 1-2 bushels upon one acre and ten rods of land.

The premium on Carrots, \$6 to Mr. Bradbury Robinson, of Greenland. The quantity was 191 1-2 bushels upon one quarter of an acre of land.

The premium on White Beans, \$5 to Simon Magoon, Esq. of East Kingston. The quantity was 11 bushels 3 1-2 pecks upon half an acre of land.

Of the sum of nearly one hundred dollars appropriated by the Society for premiums upon the different crops, the above sums of much less than one half the amount for want of competitors, are all that your committee can recommend to be awarded. The evidence of the claimants and their statements of the manner of cultivation, &c. were conformable to the regulations of the Society and are transmitted herewith for their consideration.

Your committee would here present to the society their own views of the different modes of cultivation pursued by the several competitors, with such remarks as occurred to them from the examination of the evidence in relation to their claims, if they did not feel discouraged from such labor, by a conviction, that a

difficulty exists not much in the power to produce great crops, as in so grossly erroneous opinion, with a large portion of the community, as to the expediency and utility of that system of cultivation necessary to effect that object.

The first great and common objection is, that it is *expensive and unprofitable* to the farmer. This deserves a moments consideration, and for those who do not take assertions *often repeated for proof*, it can require no more. We entreat those who make this objection, to examine the subject, and with all the certainty of mathematical demonstration to undeceive themselves. Your committee have satisfactory evidence before them, that the land on which the largest wheat crop was raised, may be fairly valued at about fifty dollars the acre.

A years interest of which sum at 6 per cent is	\$3
Cost of two ploughings, one in fall and one in spring,	3
Harrowing,	2
Two and a half bushels of seed at 9s.	3 75
Harvesting,	3
Thrashing and cleaning,	4 50

Whole cost of crop and use of land,	\$19 25
-------------------------------------	---------

Value thirty-nine bushels and one peck wheat at 9s. per bushel,	\$58 67 1-2
	19 25

Net profit on the above crop,	\$39 62 1-2
-------------------------------	-------------

One acre of corn land, valued \$50 per acre, interest on which for one year at 6 per cent,	\$3
--	-----

Ploughing in fall,	2
Ploughing in spring and planting,	5 50
Seed corn,	75
Harrow three times,	4 50
Cutting stalks, harvesting, husking,	4
Expense of manure,	50
	\$39 75

By value of one hundred bushels corn, at 67 cents,	\$67
By stocks and butts,	10
	\$77
	39 75

Net profit on one acre of corn,	\$37 25
---------------------------------	---------

But it is said the system of confining cultivation so as to secure great crops, is not actually unprofitable, still it is not the best.

First, because the same expense on more ground will yield a better income.

Again let us refer to facts and calculations.

The difference between a crop, such as the one to which the premium is awarded, and the more common one of from 30 to 50 bushels per acre, is occasioned principally by applying to one acre the quantity of manure usually distributed to three acres, with also a little more attention in ploughing.

Suppose then 3 acres of land to be planted, valued at \$50 per acre, the interest is	\$9
All the other expenses will amount as much per acre as for the best crop (except the manure) and amount as by former estimate to	\$50 15
Manure,	20
	79 15

Allow an average crop of 40 bushels per acre, at 67 cts. 120 bushels,	80 40
Value of stocks and butts,	12
	\$92 40
	79 15

Net profit of 2 acres corn,	\$13 25
-----------------------------	---------

A certain quantity of any crop raised is in

payment for the labor and expense. It is amount beyond that only, that is profit—and that great object then surely should be to increase that part of the quantity which is the profit. For instance, if 50 bushels of corn only pay the expense of cultivation, he who raises 60 bush with the same labor as he who raises 55, makes double the profit, though his quantity is increased only five bushels.

Your committee would feel bound to apologize for detaining you with calculations so plain and apparent to all who have an acquaintance with the first rudiments of arithmetic, we note the objections we have stated still every day urged, and had it not been heard in our legislation.

A second objection urged to limiting the quantity of tillage is, that the grass lands demand frequent ploughing and, if neglected, they are bound out. They do become so upon a system of running over them without dressing the plough of itself, in grass land, does very little but produce a temporary effect upon the soil, which scarcely is perceived in a second season, and the same argument that should induce us to cultivate in a manner to produce the greatest crop of corn, or grain, proves the utility of the system in relation to crops that are to succeed.

A premium is offered by the society for the largest quantity of any vegetable, profitable for feeding cattle, for which no claim is made while the keeping of stock for beef and for dairy is so great a part of the business of every farmer in this section of the country. Your committee cannot but consider the fact, that claim is made for this premium as a striking proof of a want of attention to the great object of economy in the mode of supporting cattle through our long and expensive winters. Expensive they surely are, when a stock of cattle is supported entirely upon hay. Two tons of hay is justly esteemed a very liberal crop from an acre of mowing, and suppose the expense to be but half that of growing an acre of potatoes; the same land will yield from 3 to 4 bushels, which cannot be denied to be equal three times that quantity of hay. While 1 bushels of carrots may be produced from an acre of land, by labor which may be performed in a manner and at times, much more convenient than is usually required for making hay. To those who have made such roots a part of the food for their cattle, through the winter months, it need not be said, that it is much better as it is cheaper, than keeping them entirely upon hay. No claim is made for a premium on Barley, a crop, which if not great, is always here more certain than most other grain, and always a cash article in the market.

Your committee cannot believe, that it is a want of suitable crops of potatoes, that claim is this year made for a premium in the highly valuable root. While our farmers are every day learning to appreciate its value, it is already become an extensive article of sale to whom convey it to market. Gentlemen of accurate calculation, and who have means of ascertaining, have estimated, that no less than \$10,000 was paid the last year for potatoes in the market of Portsmouth alone.

From the apparent inattention of farmers to the invitations of the Society, and from the tone of complaint, which perhaps prevails too much

the statement of your committee, they may be asked if they despair of the society and the object of its institution? We answer at once by no means. We look upon the art of agriculture, as the first employment of the human race in their state of primeval innocence. Their occupation in the garden of paradise was "to till and to dress it." We look upon it as that pursuit of all others best adapted to our country and government. If the estimates, which we have made upon the best evidence, are not entirely erroneous, we have shown it to be an employment, that yields its most liberal reward. Farmers do not accumulate such fortunes as the money letter, by his 10, 12 or 20 per cent. may Jew out of his unfortunate neighbors, it is not because his per cent. is not as great—but because the usurer has acquired that habit of economy in fractions and fragments, which makes his estate.

Still your committee believe the science of agriculture, while it is pleasant and profitable, to be one of the most complicated and least understood of any to which the attention of man has been directed.

In this country particularly, there has been no occasion for its study. In our new lands, we have opened our fields, the husbandman was called upon for little, save the seed—and took his crop asking no questions why or wherefore.

While every other, the simplest art or trade as its instructors, every profession its tutors and lecturers, neither our schools, academies, colleges, have ever placed a book on this science upon the long catalogue of their studies, the consequence is, agriculture is pursued by inheritance to customs and to traditions handed down from a period in our country and a state society, which makes them in many respects suited to the present time.

Your committee are no advocates of speculative innovations, merely for their novelty, but they would not with the obstinacy of the Scotchman continue to go to mill with their corn in the end of the bag, balanced by a rock in the other, merely because it was the practice of their ancestors. And it is with pleasure your committee can state, that a spirit of rational improvement is gradually, although slowly making progress in the community. Our literary institutions, many of them seem to have discovered that the great "art of all arts" is not unworthy of their attention. Gentlemen of learning and scientific research have "taken hold of the plough," with a resolution that will not easily be turned back. The nature of our different soils—their adaptation to different crops—the properties of manures, and the comparative advantages of different modes of cultivation, begin to be understood, and their importance to be felt. Let these considerations then cheer us amid the partial discouragements that present surround us. Our own interest—the interests of our fellow men—of our country, demand perseverance in our efforts. They will ultimately be crowned with success.

ICHABOD BARTLETT,
BENJAMIN PILSBURY,
JOSEPH W. MARCH.

Oct. 15, 1823.

LONDON, Oct. 15.—*Velocity of Sound as a Measure of Distances.*—The Philosophical Transactions of the present year contain an able paper

from J. Goldinham, Esq. F. R. S. on the velocity with which sound travels under various circumstances. The paper is far too voluminous for our columns; and we shall merely state, that the observations were made by noticing the intervals between the flash and the report of two twenty four pounders, at known distances from the observer, who was stationed at the Madras Observatory. The results of his numerous experiments confirm those of previous observers, that the mean velocity of sound is about 1142 feet per second.

We have long been of opinion that the velocity of sound might be rendered available for measuring distances for a variety of purposes, such as estimating the distance between ships, or any given objects at sea; and with still greater accuracy for measuring distances on land, which might be accomplished in the following manner:—Suppose it be desirable to determine the distance of a ship from a battery, or other station on shore provided with cannon. With a fort, where a morning and evening gun are fired, the object can be attained without any concert with the shore, by an observer on board the ship being provided with a tolerably good seconds' watch, and noticing the interval between the flash of the gun and the report. This may be done to the fraction of a second, by counting the beats of a watch during the interval. Now as the ordinary seconds' watch makes about 25 beats in 10 seconds, the distance may be very nearly estimated by allowing 456 8 or 457 feet for the beat of a watch. Thus 40 beats, or 16 seconds, would give a distance of 6091 yards; or about 60 yards short of 2½ miles. Although the flash of a gun is not visible at any considerable distance by day light, yet on a clear day the smoke issuing from a large piece of ordnance is almost as instantaneous as that of the flash, and by attentive observation it would give almost equally accurate results.

In the department of Military Engineering, this method of determining distances would be extremely valuable; as it might be applied in many instances where actual measurement would be quite impracticable; such as across a river or ravine, or in case of the occupation of the intermediate ground by an enemy.

In Civil Engineering and Land Surveying, it might also be applied with considerable advantages, in the following manner:—Two persons being stationed on elevated ground within sight of each, one being provided with a strong fowling piece, (or rather a blunderbuss for greater effect) and the other with an ordinary seconds' watch.—The interval between the flash and the report, as before mentioned, is to be carefully noted by the observer; who for the sake of greater accuracy, might be assisted by a third person, in order to mark the instant of the discharge. It might also be preferable to choose the dawn of day for the operations in order to render the flash from the fire arms more distinctly visible. By repeating the experiment a few times, and taking the mean of the observations, a sufficient degree of accuracy would be attainable by this method for any of the ordinary purposes of land surveying. It is proper to remark that, should the wind set towards the observer, at the time, from five to ten feet per second should be added to the estimated distance. If, on the contrary the wind

blows from the observer, the same amount is to be subtracted from the distance, as estimated at the rate of 1142 feet per second.

The distance of a thunder clod from an observer might also be very nearly estimated, by noticing the interval between the electric discharge and the thunder. This, however, would be a mere point of curiosity, while in the former cases (and others which might be named) this mode of measuring distances would be at once economical, and sufficiently accurate for general purposes.

From the Boston Evening Intelligencer.

Hydrostatic Press.—We have seen a machine of this description, made in this city by Mr. Eben A. Lester, which, as far as we can judge, is quite perfect in its mechanical construction. We are not aware that the Hydrostatic Press has often been manufactured in this country; but we are confident from the information we have obtained that none superior to this has often been received from G. Britain. The power of the machine extends to a pressure of 150 tons; it is generally employed, at from 63 to 100 tons, which is sufficient for all common purposes. The use of these presses, we believe, has generally superseded that of the improved screw press, in England; and upon the slightest inspection, it is evident they possess the most manifest advantages over all others. A screw is one of the mechanical powers most impeded in its operation by friction; but in the Hydraulic [*Hydrostatic*] Press the effect of the screw is produced by forcing water, with a forcing pump, under a metallic cylinder, confined in a cylindrical tube of great strength, by which it is raised, against a fixed iron plane above; and the power of pressure which may be given is only limited by the strength of the machinery itself. It is clear that in such a machine there can be but little friction; hence one source of the advantage it possesses over the screw press. A person with a moderate exertion of his own strength applied to the handle of the forcing pump, can produce a pressure of 100 tons by merely injecting a small quantity equal to a common tumbler within the hollow iron cylinder below. The Hydraulic [*Hydrostatic*] Press exhibits one of the most interesting instances of curious experiments applied to the common purposes of life, that can be found among the multiplied examples of ingenious machinery.

From the Danvers Courier.

Voracity of the Cod Fish.—A short time ago a cod-fish, of the rock species, was caught in the bay of Luce, and dissected by a correspondent, on whose accuracy we can rely. In the stomach of this aquatic glutton there were found no fewer than seven lobsters, besides fragments of smaller fish. One of the lobsters weighed 15 ounces, and three of them, which were taken out alive, looked as fresh and fair as if they had never "crossed the craig" of the voracious cod. The gastric juice of the cod must of course be extremely powerful; but if the largest lobster had used his fore finger and thumb to as good purpose as we have seen divers of his kind do, he might have easily, we think have sprung a leak under the lower fin of his devourer, and, by a trifling exertion of muscular power, piloted his way back to father Ocean.

Extracts from an Address delivered before the "Society of Middlesex Husbandmen and Manufacturers," on their anniversary at Concord, Mass. October 2, 1823. By Josiah Adams, Esq.

"Permit me, my brethren of the Society, to congratulate you that, in our meetings here from year to year, we are cheered with the smiles of the public.—All classes seem to have united in patronizing the first, and the noblest of the arts. The learned, and the unlearned, have combined for mutual benefit, and those jealousies, which, in other concerns, arrest the progress of improvement, are not known among us—scientific speculations, adapted to practical purposes, are read with avidity, and weighed with candor. The great change, in this respect, which has taken place in the public mind, must be particularly refreshing to the early members of this Society, who began and continued their useful exertions, against the blasts of ridicule, and the tide of popular prejudice.

"In regard to the propriety and utility of Cattle Shows, there was formerly much difference of opinion. The objects of them were not understood, and they were opposed, even by men of good sense, as causing a waste of money, and as having no tendency whatever to advance the agricultural interest. They were considered an addition to the number of idle holidays, and great vice and immorality were predicted as their certain attendants. And though *Derry Fair* and *Concord Courts* were going fast out of fashion, a Cattle Show was worst of all!—and the poor, innocent little town of Brighton, was viewed like the great city of Nineveh, in which were "four score thousand souls, that knew not their right hand from their left, and also much cattle;" and whose refusal to preach against it, was denounced by the great land-whale of public opinion. In short, men would strain at a PLOUGHING MATCH, and scallow a HORSE RACE!

"But such prejudices are now extremely rare. Great decorum has prevailed; authority has been given by law to preserve order, and, on these occasions, we have the satisfaction of meeting our most useful and respectable citizens—our most considerate and industrious farmers. Indeed it seems now to be generally admitted, that to those meetings, and to the exertions connected with them, we are principally indebted for the wonderful improvements which have been made in husbandry. A comparison and interchange of opinions and views have been effected—a unity of feeling and action—a spirit of emulation and a just self-respect have been created, which have greatly improved the situation, and multiplied the enjoyments of the farmer—have given him new views of his condition new motives to exertion, and opened upon him bright prospects of comfort and usefulness, which he had supposed confined to other classes of society.

"The power of habit, and the charm of hereditary custom, have been gradually subdued. Men have learned to think, as well as to labor—and not only to think, but to listen to the suggestions and speculations of others. Men of leisure, of property, and of talents, have aspired to become acquainted with the principles of good husbandry, and, by their valuable speculations and experiments, have very much assisted practical men in their efforts to improve.*

It is much to the honor of the yeomanry of New-England, that it is growing less and less fashionable to undervalue philosophical disquisitions and experiments. Men read and think on the philosophy of agriculture, as they do on all other subjects. The farmer, whose education does not always enable him to see the connexion between cause and effect, does not feel bound, by the fashion of the times, to disbelieve the existence of such connexion; and this is but applying that common sense to the management of his farm, which he is accustomed to use on all other occasions. Most men are necessarily ignorant of the process of the astronomer in calculating an eclipse—in determining the moment of the sun's rising and setting—and the exact times in which the planets perform their revolutions; but they do not therefore question the truth of his predictions; and the man, who should avow a disbelief of the Almanac, would be accounted the greatest of all infidels! Implicit faith is not, and indeed should not, be yielded to every theory, which finds its way to the public through the press—some caution is undoubtedly necessary in adopting new methods of cultivation—particularly those, which have not been fully proved by experiment; and even those methods, which have been found profitable under certain circumstances, may be useless, and perhaps very detrimental, in all other cases. A great variety of things are to be considered—the difference of climate and of soil—the facility of obtaining manure—the price of labor—the distance from the market—and a multitude of other incidents, which will readily occur to a thinking and discreet mind. A man of such a mind will not be deterred from making improvement, by any seeming difficulty in determining what may be profitable. He will see that husbandry is indeed an art of a very superior order. Not like some of the mechanical arts, which are little else than mere habits, which, being once acquired, are pursued with little or no mental exertion. He will perceive that his progress depends not so much on the labor of his hands, as in assigning to those hands their proper employment. And, by thus dividing his task between the body and the mind, he lessens his toil—increases his gains—and procures a new source of mental enjoyment.

"The attention which is paid in New-England to the subject of EDUCATION, has given to all classes a source of happiness, which is enjoyed in no other country; and some, at least, of our practical farmers are capable of considering agriculture in its connexion with the sciences. Its dependence on the science of chemistry in particular has given to our subject an interest and importance among the learned, which has proved of great public utility. Chemistry teaches the simple substances of which the material world is composed—the different compounds which nature is continually forming in the animal, vegetable, and mineral kingdoms, and the decompositions, which consequently take place; together with the manner of producing the same effects, by the assistance of art. And, by showing what simple substances are necessary to the formation of certain compounds, it informs us what kinds of soil, and

to the trial of uncertain experiments.—The community are therefore much indebted to those who have so readily made the necessary expenses.

what manures, and other substances, are to be united, to bring forth the various products of the farm. It teaches us that two sub-stances, which singly are of no value, if united in certain proportions, will form a valuable soil; and that the addition of a third, which may be, in itself, perfectly harmless, may render the compound use less and barren. We ascertain, for instance the proportions in which clay and sand should be mixed, and when, and in what proportions lime, ashes, or vegetable substances should be added to the composition, and this, with as much certainty as attend experiments in other branches of science. *Agricultural chemistry is essential to good husbandry, and every farmer should be acquainted with its general principles.*

"There is no idea more unfounded," says Sir Humphrey Davy, in the introduction to his lectures on agricultural chemistry, "than that a great devotion of time, and minute knowledge of general chemistry are necessary for pursuing experiments on the nature of soil, or the properties of manures. Nothing can be more easy, than to discover whether a soil of fervesces, or changes color, by the action of an acid—or whether it burns when heated, or what weight it loses by heat. And yet these simple indications may be of great importance in a system of cultivation. The expense, connected with chemical enquiries, is very trifling. A small closet is sufficient for containing all the materials that are required. The most important experiments may be made by means of a small portable apparatus—A few phials, a few acids, a lamp, and crucible are all that are necessary."

"Next in importance to the great business of preparing for a better world, is to know how to live comfortably in this; and the goodness of the Creator appears in nothing more conspicuous, than in having made the support of ourselves and families an essential part of religious duty. "Remember the sabbath day to keep it holy," is an injunction of no greater authority, and no more intended to form our moral and religious character, than the command, "six days shalt thou labor and do all thy work;" and, since "he that provideth not for his own house is worse than an infidel," it is therefore a religious duty to improve ourselves, and each other, in a knowledge of the arts, by which property is acquired—and as no one of these can rank in importance with the art of agriculture, we have reason to feel much satisfaction in finding ourselves again assembled, for such excellent and noble purposes. And, to strengthen our exertions, allow me to conclude with a passage from the author before cited

"Many of the sciences are ardently pursued, and considered proper objects of study for all refined minds, merely on account of the intellectual pleasure they afford; merely because they enlarge our views of nature, and enable us to think more correctly with respect to the beings and objects which surround us. How much more then is this department of enquiry worthy of our attention, in which the pleasure resulting from the love of truth and knowledge, is as great as in any other branch of philosophy, and, in which it is likewise connected with much greater benefits and advantages"—*Nihil est melius, nihil uberius, nihil homine libero dignius.*

"Discoveries made in the cultivation of the earth are not merely for the time, and country,

* The pecuniary means of most men are inadequate

rich they are developed—but they may be considered as extending to future ages, and as tending to benefit the whole human race by affording subsistence to generations yet unborn: as multiplying life, and providing for enjoyment."

From the American Farmer.

Poswellton, Philad. County, July 1, 1823.
SIR,—Your profitable management, more, than the high state of cultivation, which the officers of the society found your example to desire, not merely a statement of system, you pursue, in the preparation of soil—the arrangement of your fields—the sowing of your crops—but the mode of securing your fodder—feeding your cattle—and the management of their manure. I was struck, by the appearance of your stock, and gratified, at the same time, that our opinions, and practice perfectly coincide, in the preparation of hay, and disposition of it in hay houses, instead of huge

hay stacks. I have thought, the parade of Pennsylvania about as profitable as the decoration of the blue waggons, or the musical bells attached to our teams. The ingenious mode of depriving our grasses, of their most nutritious parts, is so absurd, that it has since would have been abandoned, I hope, had not our prejudices in favor of the old way, which generally keep practical farmers right, in this instance put us all wrong.

In bad weather, most crops of grasses, can be preserved without being shaken from the swarth. The uniform practice for many years has been to mow grass to remain nearly two days, undisturbed, to gather it by an horse rake, cock it in neat part of the day, salt it, and place it in a hay house, which admits a free circulation of air. My clover like yours, retains much of its color, its blossoms, and leaves. The advantage of pitching hay, from the carriage into the hay barn," does not counterbalance, the expense of labor in preparing, the loss of nutrient in drying, and the great danger of fire in storing, as well as from the escape of moisture, which so often in this climate, attracts vermin, to the utter destruction of the building. The hopes of the farm.

The convenience of feeding, has also been urged to aid the arguments, in favor of the Pennsylvania barn. We owe much of our success to the industry, care, and skill, of our German population, but I think, it may be questioned, whether the expense they incur, in the arrangement of their farm buildings, is not often mischievous, not merely useless, but dangerous, to the health of their cattle, and diseasing them with bad hay. It is scarcely possible in this country, where the changes of climate, are so rapid and severe, to guard farm stock, from the effects of cold, when they are made warm throughout the winter, and necessarily, left exposed to the effects of storms, during part of the day. I am convinced, that milch cows, and very young calves, require protection from cold—all other stock, should be guarded from wet, and currents of air, and fed with more appetite, digest with more vigor, and encounter accidents with less danger of harm, when they be confined within thick stone

walls, inhaling an impure atmosphere, from which by the instinct of nature, if not thwarted by the ill judged contrivance of man they would fly.

I would suggest, that the position for the farm yard be selected as usual at the foot of a small hill, of which the southern side, should be cut in such manner, as to admit the erection of a barn sufficiently large for all its usual purposes, except that of holding hay, and feeding cattle. Room for pitching to the South, and sufficiently capacious to protect all the hay, straw, fodder, and stock of the farm should be extended at both gable ends. For the support of the fodder lofts, and roofs, pillars of brick, or stone, should be erected at proper intervals; for the security of the bank, and the road at its edge—a wall somewhat higher, than it, should be built—a space of two feet, should be left, between the northern side of the loft and the wall. Racks should be placed perpendicularly, with their outer edges, exactly corresponding, and parallel with the wall, and side of the loft. Thus a space, of two feet would remain between them and the wall, to be filled with hay. A long shutter, sufficiently wide, may be secured by hinges, attached to posts, on the outer side of the wall—in order that when the rack shall have been filled, by pitching from above, it may be closed, at a proper angle to exclude rain or cold air.

Stalls for cattle, pens for sheep, and calves, should be at fit distances placed beneath the hay—pavings, and gates, might secure them on the southern, or outer side. The hay being exposed on two of its sides, would require infinitely less drying, than if pressed closely, in a great mass, within the thick walls of a barn. It is scarcely to be believed, by those, who have not seen the experiment, how little drying, grass requires, when it is to be salted, and thrown lightly, into an open hay house. By beginning at one end of a long loft, and discharging the loads, so as to not more than half fill it, until the hay be extended to the other, by the time, that the end at which the farmer began, shall be quite filled, his hay, in despite of the state, in which it has been hauled, will be sufficiently dry. The advantages, I propose, are the saving of labor in making the hay, of money, in building the barn, of nutrition in not exhausting the grass by unnecessary exposure, to the rays of the sun; and to practical farmers, what to them, is of consequence, a return to their pockets, in profit on cattle, which after being exposed from January to July upon hay, and grass alone, may be exposed on Philadelphia shambles with credit to the feeder, as yours have been shown. I am yours, &c.

JOHN HARE POWELL,
Corresponding Sec'y, Penn.
Agricultural Society.

From the Cook's Oracle.

BOILING.

This most simple of Culinary processes is not often performed in perfection,—it does not require quite so much nicety and attendance, as Roasting. To skim your pot well, and keep it really boiling (the slower the better) all the while,—to know how long is required for doing the joint, &c. and to take it up, at the critical moment when it is done enough,—comprehends almost the whole art and mystery. This, how-

ever, demands a patient and perpetual vigilance, of which few persons are capable.

The Cook must take especial care that the water really boils all the while she is cooking, or she will be deceived in the time; and make up a sufficient fire (a frugal Cook will manage with much less fire for Boiling than she uses for roasting) at first, to last all the time, without much mending or stirring.

When the Pot is coming to a boil, there will always, from the cleanest Meat and clearest Water, rise a Scum to the top of it: proceeding partly from the foulness of the meat, and partly from the water,—this must be carefully taken off as soon as it rises.

On this, depends the good appearance of all boiled things.

When you have skimmed well, put in some cold water, which will throw up the rest of the scum.

The oftener it is skimmed, and the cleaner the top of the Water is kept, the cleaner will be the Meat.

If let alone, it soon boils down and sticks to the Meat;* which instead of looking delicately white and nice,—will have that coarse and filthy appearance we have too often to complain of, and the Butcher and Poulterer be blamed for the carelessness of the Cook in not skimming her pot.

Many put in Milk, to make what they boil look white; but this does more harm than good:—others wrap it up in a cloth:—but these are needless precautions, if the scum be attentively removed, Meat will have a much more delicate color and finer flavor than it has when muffled up. This may give rather more trouble—but those who wish to excel in their Art must only consider how the processes of it can be most perfectly performed;—a Cook who has a proper pride and pleasure in her business, will make this her maxim on all occasions.

Put your Meat in cold water,—in the proportion of about a quart of Water to a pound of Meat—it should be covered with water during the whole of the process of Boiling—but not drowned in it—the less water provided the meat be covered with it,—the more Savoury will be the Meat, and the better will be the Broth.

The water should be heated gradually—according to the thickness, &c. of the article boiled—for instance, a Leg of Mutton of 10 pounds weight, (No. 1.) should be placed over a moderate fire, which will gradually make the water hot, without causing it to boil for about forty minutes—if the water, boils much sooner, the meat will be hardened, and shrink up as if it was scorched—by keeping the water a certain time heating without boiling, its fibres are dilated, and it yields a quantity of scum, which must be taken off as soon as it rises.

If a vessel containing water be placed over a steady fire, the water will grow continually hotter till it reaches the limit of boiling, after which the regular accessions of heat, are wholly spent in converting it into Steam—the Water

* If, unfortunately, this should happen, the cook must carefully take it off when she dishes up, either with a clean Sponge or a Paste-brush.

† Cooks, however, as well as Doctors, disagree; for some say, that "all sorts of fresh meat should be put in when the water boils." I prefer the above method, for the reason given—gentle stewing makes the Meat, &c. tender, and still leaves it rapid and nutritious.

remains at the same pitch of temperature, however fiercely it boils. The only difference is, that with a strong fire it sooner comes to boil, and more quickly boils away, and is converted into Steam."

The Editor placed a Thermometer in water in that state which Cooks call *gentle simmering*,—the heat was 212°—i. e. the same degree as the *strongest boiling*. Two Mutton Chops were covered with cold water,—and one *boiled a gallop*—and the other *simmered gently* for three quarters of an hour; the Flavor of the Chop which was simmered was decidedly superior to that which was boiled; the *Liquor* which boiled fast, was in like proportion more savory, and, when cold, had much more fat on its surface: this explains why quick boiling renders meat hard, &c. because its juices are extracted in a greater degree.

Reckon the Time from its first coming to a boil.

The old rule of 15 minutes to a pound of meat, we think rather too little; the slower it boils, the tenderer, the plumper, and whiter it will be. (To be continued.)

Montreal, Nov. 11.—A strange accident took place in a chemist's shop a few days since. A person having put a gallon or two of alcohol upon a stove in a tin vessel, the liquid took fire and exploded with a violent shock. The whole room was filled with smoke; a person endeavoring to escape by the shop door, had opened it partly, and merely put his head out, when the sudden expansion of the air in the room closed the door, caught him by the head, and held him for several seconds, until the conflagration ceased. No other injury than the loss of the liquor, and the fright suffered by the persons present, was sustained.

It is computed that 55,000 barrels of Pot and Pearl Ashes, will have been shipped during the season from the Port of Quebec. This exceeds by nearly twenty thousand the number shipped last year, which was about 32,000.

NEW ENGLAND FARMER.

SATURDAY, NOVEMBER 29, 1823.

Letters of Agricola on the Principles of Vegetation and Tillage.

We have frequently, in the course of our editorial labours, availed ourselves of the information contained in an excellent work on husbandry, entitled "*Letters of Agricola*," &c. written in Nova Scotia, by JOHN YOUNG, Esq. we believe a native of Scotland. Having learned that a few copies of that treatise are for sale, in this city, by Messrs. Wells & Lilly, we are induced to attempt some sketches of its character and merits, with a hope to be instrumental in recommending it to the attention of New England Agriculturists.

If the merits of a literary or scientific work may be correctly estimated by the effects it has produced—the value of the tree judged of by its fruit—the "*Letters of Agricola*" may claim a very high standing among the productions of the best writers of the age who have devoted their powers and faculties to the most useful and important of human pursuits. Before this publication, rural labour in Nova Scotia was held in great contempt, and to handle a spade, or direct a plough, was deemed an employment of the meanest and most degrading kind. "Tillage was so much neglected that neither oats, barley, rye, Indian corn, nor wheat, were raised in

sufficient abundance to answer half the domestic consumption. Oat meal and pot barley were regular articles of import from Britain, and the latter article was also brought largely from the United States. Indian meal, rye and wheat flour were landed by thousands of barrels from Boston and New-York not only to supply the inhabitants of the sea ports, but also the farmers in the country." The publication of the "*Letters of Agricola*" (whose patriotic and scientific exertions received every encouragement from the Governor, Chief Magistrates, and other men of high standing, influence and reputation in the Province) had an effect, which can scarcely be paralleled in the history of arts, or the annals of human improvement. "In the history of no country has there ever been recorded a more radical and instantaneous change, than has been witnessed in Nova Scotia. Improvement has proceeded with such gigantic strides, that already the point is out of sight from which we started; and although the whole has been effected in little more than three years, it is with difficulty that we can bring ourselves to the belief that the provincial husbandry was in such a state of barbarism at its commencement." Agricultural societies were established, cattle shows instituted, new implements and improvements of every kind, introduced, and Nova Scotia, instead of being dependent on other countries for bread corn, and other articles necessary to feed its inhabitants, was enabled not only to supply her wants from her own resources, but to export wheat, and other surplus products of her soil, in considerable quantities.

This great and beneficial change of public opinion, the knowledge of rural economy, and the consequent amelioration of the state of society, and condition of the country was effected by the publication of the "*Letters of Agricola*." Other causes were, no doubt, auxiliary but those "*Letters*" were the cause of those causes. The writings of Mr. Young, (first published in the Acadian Recorder, and circulated throughout the Province,) furnished the spark, and kindled the flame which pervaded the country. As the author expresses it, "while I thus continued to write, and he [Lord Dalhousie, then Governor of Nova Scotia] to approve, the first characters for rank in the Metropolis did not long stand as idle spectators but touched by the lambent flame of patriotism, they hastened within their respective spheres of influence to scatter and propagate that sacred fire, which soon burst out with irrepresible and extinguishable brightness."

The work is written in an easy but at the same time an elevated style. The author uses some hard words, but a farmer with a common country school education may understand most of them, and those which he does not comprehend, it may be well for him to ascertain the meaning of by methods which are at the command of every farmer in New England, who is in what we call comfortable circumstances.

"Cotting's Introduction to Chemistry," *Conversations on Chemistry*, and other cheap elementary works on that science will furnish an explanation of all the terms made use of by the writer, which are not sufficiently explained as they are introduced. Prosperity is one of the greatest merits of the book, but some parts of it will need to be studied, and not rapidly hurried over as if it were a novel or romance, calculated merely to amuse. It has the merit of being better adapted to the climate and soil of New England than any European writings upon agriculture. Every page evinces that the writer is not a mere theorist, but has a practical knowledge of the art as well as the science of husbandry. The reputation of the book, however, is to well established to require our testimony in its favour. We shall therefore, conclude this article by merely

naming some of the subjects treated of, which, we assure our readers that they are very ably dis- will better recommend the work than the most rate eulogy.

After describing the low state of Agriculture in the Province, the author recommends the establishment of agricultural societies, and gives a brief sketch of their constitution and objects—describes physical causes which influence and affect it—shows that the cultivation of a territory moderate rigor of its climate, and contrasts the present with the state of Europe as delineated by classical writers. He devotes two chapters to proving that a gradual improvement has taken place in the climate of Nova Scotia since the first settlement of that country, to the prevailing prejudice which existed against the climate of Nova Scotia; and to show from the nature of its vegetable productions, that it will ripen all the crops. This part of the book is replete with citation to our cultivators, who reside in the northern part of New England, and entertain an opinion that the country is too cold for them to obtain a livelihood of course they must either starve or emigrate to the warm Mississippi countries. The author then takes up the topic "of soil as the bed of vegetation, and lays down the simpler elements of agricultural chemistry;" "gives some hints on the food of plants;" "Enumerates the uses which the soil serves in vegetation;" "Describes the physical properties of the four earths which chiefly constitute soils, and expresses the advantage of chemically analysing the latter;" "Describes the formation of soils as resulting from the disintegration of the primary and secondary rocks;" "Enumerates the purposes in agriculture served by the different kinds of tillage;" "Treats on ploughs, and explains on the benefit which would be gained by the introduction of the drill machinery;" "Treats on the hand roller, threshing mills, flails, the reaping machine, the patent sward cutter, the cultivator or grubber;" "Dilates on the nature of the animal and vegetable putrescent manures;" "Shows how water may be retained the gaseous and soluble principles of the putrescent manures;" "Discusses the doctrine of fertilization, and explains the nature of composts;" "Sets forth the nature and uses of peat, and its conversion into manure;" "Illustrates the character of fossil manure, the mode of burning it, the manner in which it should be applied, its effects on vegetation, tests of its sum, phosphates of lime, magnesia, burnt clay, &c." "Enters on the natural obstructions in the soil;" "The trees of the forest;" "The inequalities of surface of the earth, which are preventive of tilth, stones, rocks, wetness, principles of draining;" "Gives a view of the cultivation of land as affecting the individual—society—and national wealth;" and "concludes with considering land in relation to its employment as capital."

Such are the topics of this work, and as we said before they are discussed very ably. Some things in it are local, and not particularly interesting to any but the inhabitants of Nova Scotia. But, on the whole, we know of no foreign work of its price, (which is \$2.50 in boards) which can claim any competition with the "*Letters of Agricola*," as a treatise adapted to the use of New England Farmers.

Fire.—In Dorchester, on the 26th inst. a large warehouse was consumed by fire. This building was situated in the Printing Office of Mr. R. Bannister, printer and publisher of a religious paper, entitled "*The Monitor*." All the printing apparatus, &c. fell a prey to the devouring element.

FOREIGN.

n.—The war in that country appears to be near a end. The French troops are embarking for at the date of the last accounts, and their com was expected to arrive at Paris in the begin December. The French have celebrated their over the liberty and national independence by is and merry meetings. A fair article of the t. states that a general amnesty or act of obli- past officers has been passed, from which only the Spaniards are excepted. The last intelli- from Gibraltar has been received by the way of and comes down to the 18th of October. At the English Ambassador, Sir William A'Court, out to proceed to Ferdinand's Court to resume negotiations.

ish America.—Accounts from Campeachy re- Guatemala are in a state of anarchy. The mixture of white Europeans, Creoles of all shades, free blacks and slaves, each jealous of the oth- all desirous to be superior, must produce very scenes, should a civil war succeed to anni- the centre of this territory, the British have pectable and flourishing establishment of Hondu- have conciliated the affection of the neighbor- of what is called the *Mosquito Shore*.— sing has been educated in England, is a Chris- a great friend to the British nation, and to ary establishments. He can command nearly arriors, and in the event of a civil war, would ly place himself and nation under the protection British.

is in force in Holland which forbids school- receiving as pupils, children who have not had all pox, or been vaccinated.

esting to the Proprietors of Steam Packets, &c.— stand that Sir Humphrey Davy has, within month, discovered that the application of a gas, fifteen times heavier than the atmosphere, mechanism of a steam engine, will produce a fully equal to that which now results from the tion of steam. The great obstacle which stands way of the general and immediate introduction of this gas is the difficulty of confining it. The constructing convenient vessels, sufficiently for that purpose, Sir Humphrey proposes as ym, the solution of which must be attended with able benefits to this country.

G. T. Scobell, R. N. has recently submitted to Board of Admiralty, a plan for applying impelling in periods of calm and smooth water, to the the British Navy. It is applicable to every men of war, from the largest to the smallest, which may be worked by hand wiches or the t, and are so constructed that they may be dis- with facility, and taken on board in seven or minutes. The principle is available to steam ves- it would materially alter their character, extend ss, and increase their safety.

DOMESTIC.

icious Accident.—On the 23d ult, two young w- attempting to ford the Ousatonic river in South- on the horse took a wrong direction, and stum- deep water, one of them was drowned, and the eaped by her clothes catching on the saddle, by means she was dragged ashore.

Phineas Johnson (aged 43) was drowned on 7, the 18th inst. while attempting to cross the anticut river on the ice, about a mile north of this e. The next day his hat was seen under the ice; it was the first intimation given, of his condition. ly was found on Thursday, and on Saturday it died.—*Bellevue Falls Intell.*

—On the 31 instant, nearly 12 o'clock at night, flour mill owned by Mr. Ormsby, Cincinnati, as consumed by fire, and but a small part of its es were saved. The cause of the combustion, has not been stated. Loss estimated at \$100,000.

Wednesday morning last, the large tavern of Mr. in B-ffast, Me. was consumed by fire, and sad- ck, his amiable daughter, aged 16 years, perished

in the flames. The fire communicated to the dwelling house of George Watson, Esq. formerly of this city, to the stores of John Angier, Esq. and Mr. S. R. Merrill, and five or six barns, all of which, with a part of their contents, were destroyed, notwithstanding the spirited exertions of the citizens to save them. The Editors of the *Belfast Gazette* and *Patriot*, add.—"Mr. Angier's store is adjacent to our office, and we are now printing this while our friends are anxiously protecting us from the flames. A short time since it was thought a large portion of our village could not be saved from the de- vouring element; but we hope the danger is subsided. We have neither time nor heart to add more particu- lars."

The Carding, Furling, and Dying Factory of Capt. Goodwin, of Bangor, Me. with all the machinery, was destroyed by fire the 27th ult. Loss estimated at \$9,500 dollars.—*Boston Centinel* of the 22d inst.

Fatal Accident.—A young man by the name of Lewis K. Upham, of Bennington, Vt. was killed, by the ac- cidental discharge of a gun, while on a hunting party. He survived the wound about 33 or 40 minutes after the ball passed through his body.

Miss Eliza Parsons, of North Yarmouth, Maine, has wrought a bonnet of native grass, said to have been equal to any exhibited in Massachusetts or Connecti- cut; a lady of Portland purchased the bonnet at \$30.

Extraordinary Crop.—Ephraim Wood, Esq. of Cam- den, sowed 5 bushels and 3 pecks of rye in September, 1822, on about 5 acres of ground newly cleared of the wood, which produced 240 Bushels—over 40 bushels to the bushel sowing, and about 43 to the acre. Its be- ing sown early and on good ground occasioned a large number of shoots to spring from one root—in one bunch was 140 stalks containing 4379 kernels, the production of one single grain! Would not our crops of winter rye generally be much better if the seed were sown much earlier than usual?

A Warning to the Intemperate!—Mr. Silas Graves, of Hatfield, Mass. of great property but no family, committed suicide in that town last week. He had lately become intemperate, and his mind had been haunted with continual fears of poverty, which are supposed to have occasioned the melancholy act.

Extensive Fraud.—We learn that money to the amount of eight thousand dollars has been drawn out of the Branch Bank of Pennsylvania, at Lancaster, by means of checks forged in the name of Mr. Jacobs, iron master, Lancaster county.—The last of these checks was presented for payment about a month ago, but it was not till this week that the fraud was discovered.

[Phil. Gazette.]

Murder.—A man was found mangled in a shocking manner this morning, in Water street. A rope was fastened round his neck, and it is supposed the perpetrator of the deed was dragging his victim towards the water, but was interrupted.—*New York Statesman.*

NOTICE.

SUBSCRIBERS indebted for the first volume of the Farmer, are earnestly requested to make immediate payment at this office. The sum due from each is small, but the aggregate amounts to a large sum, and unless received soon, the subscriber will suffer very serious inconvenience in consequence.

Nov. 29, 1823. THOMAS W. SHEPARD.

NEW ENGLAND FARMER.

FOR sale by WELLS & LILLY, No. 98, Court St. the New England Farmer, or Geographical Dictionary, containing a compendious account of the Ways and Methods in which the important art of Husbandry, in all its various branches is, or may be pursued to the greatest advantage in this country. By SAMUEL DEANE, D. D. &c. Third edition, corrected, improved, greatly enlarged, and adapted to the present state of Agriculture. Price, neatly bound and lettered, Two Dollars. November 1.

FARMER'S ALMANAC, FOR 1824.

FOR sale at this Office, the Farmer's Almanac for 1824. Nov. 24.

JACK FOR SALE.

BARBAROSSA, a Jack, bred by the subscriber, from a large Spani-h Janet, and sired by an imported Maltese Jack of the pure *Onagra* stock, is offered for sale. He is now two years and four months old, measures 14, and will, when at his full growth, undoubtedly exceed 15 hands in height—uniting the bone and power of the large Spanish breed, with the spirit, activity and respectability of the Maltese. At the late exhibition at Brighton, he was pronounced, by several gentlemen of respectability, who have examined this species of stock in Spain, the Islands in the Mediterranean, and in South America, to be superior to any they ever saw.

BARBAROSSA is perfectly docile and kind, was kept with a Filly immediately after weaning, and has *propensities*, seldom found in imported Jacks, which must enhance his value in the estimation of those accustomed to breeding mules. A full warranty of his powers will accompany the bill of sale—and the subscriber has no hesitation in asserting that he is equal to the celebrated Jack, *Compound*, bred by Gen. Washington; (being of the same grade) and that he is superior to any now in the United States or that can be imported.

If not applied for speedily he will be shipped to the Island of Cuba, where a much higher price can be obtained than is now asked. S. W. POMEROY.

Brighton, Nov. 21, 1823.

AUTUMN.

How dear to roam along the sunny hills,
When Autumn spreads her bounties on the plain;
When Industry his garner'd treasure fills
With richest stores from fields of ripen'd grain:
When slow across the fields the ponderous wain,
Deep laden with the yellow ears, is drawn,
Lie scatter'd thick and far along the level lawn.

The winding rill along the sunny vale
Sings its sweet song to cheer the reaper's heart;
And oft its voice the pensive autumn gale
Will join, and cause the rustling leaves to start;
While scores of screaming blackbirds bear their part,
With varied notes, yet full of melody;
And troops of noisy boys, with dog and cart,
Are hasting to the hills with youthful glee,
To shake the clustering nuts from the tall walnut tree.

But soon this beautiful pageantry shall fall,
And every mellow tint of Autumn fade;
A melancholy murmur fills the gale,
And sorrow saddens o'er the yellowing glade;
Through thickening clouds the suns of autumn wade,
And beauty sits upon the hills no more;
The verdure of the wood is prostrate laid,
And soon the autumn rains begin to pour,
And down the craggy rocks the swelling torrents roar.

Such is the fortune of majestic man!
The leaves of fragrance round his forehead flow,
The laureate wreath, that gales of fortune fan,
For which he climbed so high or stooped so low;
But soon approach the tempest-clouds of woe,
To mar the beauty of his brightest day;
Yet while he mourns his fortune's overthrow,
He looks to heaven for some more glorious mead:
Thus to the autumn winds I tune my forlorn reed.

LEWELLYN.

WATER COLORS.

"Your cottons," says Flavia, "are cheating vile trash!
See! the colors all gone, though you said they would
wash!"
"Yes, madam," the shopkeeper answer'd, "no doubt,
I said they would wash—but I meant they'd wash
out."

MISCELLANY.

From the New York American.

Choice of a Wife.—There is one apology, in the increasing extravagance of the modern fair, for the ridiculous rage that exists among the gentlemen, after rich sweethearts; and maidens have a not less tenable excuse for making sure of a full purse, since an empty head is very likely to accompany it.

The really prudent, and somewhat homebred man, feels obliged to relinquish the idea of marriage altogether, or defer it to a late period, because it is justly considered a hazardous adventure to marry, on the score of supporting the expenses of a modern living. But this idea shall have a separate chapter.

The first inquiry that our young men make now, when a woman is proposed for a wife, is "is she rich?" And for variety, or a *divo*, "is she handsome?" Let a husband die and leave a rich widow; or a rich heiress drop into the

market, Lord bless us! how the beaux scamper,
— "Hound-like,
In full cry to catch her!"

If there is any shame in this state of things, if sacrificing feelings, that should have their source in the most generous and elevated considerations to "*beauty and booty*," is worthy of abhorrence; then, methinks, the present generation deserves an unenviable share of "*blushing honors*."

It is not very likely I shall have much cash to give with my daughters; and in fact, I don't want any to give. God grant they may have good sense, a wholesome appearance, unsuspected virtue, affectionate hearts, industrious habits, and then—why, if nobody wants to marry them, they shall help to comfort me in my old age, and help to bear up my spirit when about to "return to Him who gave it."

I am an old-fashioned fellow, it is true; but I recollect, when I got married, I made no account of money; and if I was going to marry again, I would look for a poor girl rather than a rich one. If I have a wife, a good one is essential to my happiness, and riches are not. The Athenian General was right:—I had rather marry my daughter to a *man*, without an estate, than to an *estate*, without a man." *London.*

From the New York American.

An interesting, but care-worn merchant, in a vacant mood and mind, entered the store of a wealthy merchant in this city, and as he paced along, his eyes rested upon an unusual quantity of silver and gold coin, which the clerks were busied in counting. His heart sunk within him as he felt the chill of November, which reminded him of the poverty of his lot and the misery of his family, and turning away in despair, he ejaculated to himself, "how happy some of that money would make me!" "What is that you say, my friend?" interrogated the merchant. The confused merchant begged to be excused:—he was not conscious of uttering any thing at the moment; at any rate, his thought was not meant for his ear. But the kind-hearted merchant would not take denial, and the poor man repeated what before had involuntarily broken from his lips. "And how much my dear fellow, would it take to make you happy?" O, I don't know! the winter is coming on apace, and I have no wood; my wife and children are but poorly clad, for I have been sick. Our wants are limited, however, and fifteen dollars would dissipate the gloom of winter." "John count this man 15 dollars." The ingenious heart *can feel* like the grateful stranger, the nobleness of such bounty, and exult for human nature that meek-eyed charity should find such kindred abode. At evening the clerk enquired, what entry he should make of the money? "O say, by making a man happy, \$15," answered the no less eccentric, than humane merchant.

A gentleman of Liverpool, scorning the vulgar method of getting a wife by advertising for one in the newspapers, has adopted the new system of issuing cards of which the following is a copy: "Notice is hereby given, that a young man of 23 years of age, in the sea-faring line, dark complexion, and rather low, is in want of a wife; an 18 year damsel will meet with a favorable reception."

The female peasants on the River Loire, France, have a mode of spinning, which bles them to perform the operation as walk along the streets and roads. The d having a long handle, is held under the arm; the spool terminates at one end in a pin pointed and made rough, so that with thumb and finger of the right hand, a twist is easily given it, which draws out the thread; The spool hanging loose it runs round. The thread is then wound and another twist is given in the same. They spin hemp in this manner with facility they watch their goats, sheep or cows, graze in the fields."—*Griscom's "Year in Europe"*

Premium Silk Handkerchiefs.—We were gratified to observe among the great variety of articles of domestic manufacture exhibited at the Fair of the Mechanic and Scientific Institution, the silk handkerchiefs which obtained the premium presented by the manufacturer Mr. Wm. Bryan; as also, the specimens of some description of goods woven at the expense of Mr. Bryan, by Benjamin Yates, an ingenious manufacturer of this city. The elegance of variety of patterns, and the brilliancy and beauty of the colors do much credit to the skill of the manufacturer. The specimens were printed by Mr. Yates, and published by Mr. Yates, a dealer in silk goods.—*N. Y. Statesman.*

We mention it as a circumstance highly interesting to the character of our city that, notwithstanding its immense population, comprising people from almost all quarters of the world, grand jury of the Court of Oyer and Term which was opened at the City Hall yesterday with an appropriate charge from Judge Edwards, was only out of Court fifteen minutes, when they returned, stating that no business had been laid before them, and they knew of none in the sphere of their duties—whereupon they were discharged.—*Ibid.*

Important improvement in Tanning.—Mr. (John) Spillbury of Walsale, Staffordshire, we understand, has succeeded in reducing the tedious process of tanning to a very short period. Skins are prepared by his process in a few days, requiring by the old six weeks or months. Moderately thick hides 5-8th of an inch thick in six weeks; these take commonly five to twelve months. The leather is in every respect equal in strength and toughness, will be superior to any hitherto produced. There is no difference in the substances employed, but only in the method of applying the principle is *pressure*. This important invention has been secured by patents for three kingdoms.—*Lon. Lit. Gaz.*

Native Opium.—Messrs. Cowley and Staines, Pennsylvania, have commenced the cultivation of Poppies for Opium. They made 60 lbs. in a year. The opium is obtained from incisions in the stem of the plant. The seed is sown in the fall. Oil is got from the seeds, and cattle are fed with the cake.

BOSTON, SATURDAY, DECEMBER 6, 1823.

No. 19.

esteem ourselves truly fortunate in having an opportunity to present to our readers the following valuable production. It communicates the results of science, sound sense, and much experience, in a style which is plain, perspicuous, and happily adapted to the subjects it discusses.

The author's medical experience has given him the opportunity to interweave with his agricultural observations useful remarks respecting the care of children; the means of preventing, some of their common dangerous diseases.

We hope that the length of the Address will deter the Cultivator nor his Consort from reading it through, again and again, till its maxims are stored in the store house of memory, ready to be produced, whenever occasion may call for their aid.

ADDRESS

Read before the "Worcester Agricultural Society," October 8, 1823, being their Anniversary Fair, Show and Exhibition of Manufactures. By Hon. Oliver Fiske.

There is no instance in the natural world, of the benevolence of the Deity is more evident, than in his accommodating the temper and fertility of every climate to the necessities of its inhabitants. Nor is his beneficence less conspicuous, in his forming man free from local prejudices and territorial attachments. He plants him a garden of Eden, as prolific as the wants in the dreary wilds of Kamtschatka, the mild and salubrious regions of a temperate climate. The Hottentot, in the indulgence of his peculiar rites and customs of his country, is grateful to his bounteous Benefactor for distinguishing favors; and, in the fervor of gratitude, commiserates the lot of man in a different life. Although civilization does not essentially alter this innate principle of man, it facilitates the means of his subsistence, and enables him to supply the wants that multiply themselves from a state of nature. In Agriculture, his first and simplest employment, as more complicated business, science is the art.

The earth is emphatically our mother. From her we are first originated; and from her we derive our support. The science of Agriculture teaches us to obtain this support with the least labor to this our parent, and with the least injury to ourselves. With this view, the primary object with every Farmer should be, to ascertain what is the most proper food for plants, and the best method of obtaining it. The first question seems to be settled. Philosophy and experience may shew the analogy between the structure of plants, and the animal frame; and chemistry may unfold the elements of food essential to both: but, with all their investigations, chemists and Philosophers may not make the Farmers. Common sense, with experience, will discover the facts most important to the husbandman; and he need not trouble himself with minute enquiries respecting the cause that produced them, and the laws by which they exist. Ignorance in knowledge is not imputable to the Farmer so much as his remissness in applying it. A judicious farmer will fertilize his ground

with substances which either actually contain putrid matter, or which are in their nature promoters of putrefaction. In whatever manner these can be most perfectly and in due quantity mixed with the soil, the greatest crops may be expected. When the vegetative or made earth is exhausted by cultivation, it must be restored by again adding the substances that first made it productive. A farmer, deprived of his food, may with as much reason expect that his body may be renovated by ardent spirit or sleep, as that his land will acquire new fertility by following rest, or stimulants. Land, naturally barren, may be benefited by stimulants, which excite to fermentation, and, of course, to a putrefaction of the various substances contained in it; but that which is barren by being exhausted of its nutriment, requires food rather than stimulus. Lime, ashes, marl, and gypsum, in such a case, are improper. They are not food but serve only as digestives. They render land more fertile, not by adding vegetative matter, but by preparing and digesting what it already contains. When all is digested, the land must be exhausted. A minute pulverizing and mixing of the soil, it must be remembered, is the agent of its fertility.

By attending to the cause of the poverty of land, the farmer can judge with certainty in what cases stimulants are to be used, and when manure is required. The more poverty of the soil is not a criterion: he must consider what has made it poor. The conclusion to be drawn from this theory is, that there is a certain limit in the fertility of the earth, both as to duration and degree; but, that there are no means of keeping it in any profitable productive state, without the constant and liberal use of manure. Stimulating dressings may conduce to large crops, for a time; but the more they increase the fertility, the sooner will they exhaust the soil—while the regular and plentiful manuring it, will constantly keep it productive.* The means of procuring manure are generally in proportion to the quantity of land the farmer keeps under good cultivation. The reciprocity of benefits between his farm and his stock,

* Some of the foregoing sentiments on fertilizing land, and the use of gypsum, &c. I have taken from a manuscript on the subject, prepared nearly twenty years since. Whether they were then borrowed, or were the result of my own reflections, I have not now the means of ascertaining. Should the reader find them elsewhere, he will have the candor to exonerate me from the charge of intentional plagiarism.

I am not insensible that more modern theory has ascribed to gypsum and its kindred substances a different agency; still I apprehend that the manner of their causing fertility is not conclusively settled. Until it be, a prudent farmer will keep the body of his soil in vigor by more certain means, and leave it to philosophers to determine whether these substances, which he will do well to add, increase its fertility, by preparing nourishment for the plant, to be imbibed from the earth by its roots, or from the atmosphere by its leaves, or both.

Some farmers have abandoned the use of gypsum, from its having ceased to conduce to fertility. The reason of this probably is, that they have relied too much on this substance, and neglected other means of keeping their land in good condition.

with the addition of every thing he can collect, which can be decomposed and is valuable for any other use, if well preserved and judiciously expended, will be an abundant supply. Our modern theories comport so well with philosophy, and are so readily confirmed by experience, that we are led to wonder that the science of husbandry should not have made a more visible progress. The reason, however, is obvious.—Agriculture, from its nature, has peculiar obstacles to encounter. So various and so complicated are our pursuits, that the time allotted to man, since the antediluvian age, is scarcely sufficient to enable him to make any considerable proficiency in any art or science. This remark applies with peculiar force to Husbandry. One year of our scanty number is necessary for an experiment; and many years are sometimes required to test its utility. Another difficulty arises from the mediocrity in the circumstances of the generality of our farmers. From this cause, they are induced to prefer the moral certainty of success, in their accustomed mode of cultivation, to the precarious chance of an untried experiment—especially as it requires more knowledge in the philosophy of nature than they usually possess, to trace the connexion between cause and effect, by which their faith in any new theory might be established. A further and more formidable embarrassment attends it. As individuals, so sanguine are we in the infallibility of our favorite theories, and so vain of our fancied merit in having investigated them, that without the sanction of some constituted body which has tested them, the public are often deceived and injured, and farmers are discouraged from making innovations on their modes of practice. The want of accuracy in experiments is often as fatal to the result as the proceeding upon false data. To what other cause can we impute the various and contradictory opinions derived from our experiments?—Take the *Potatoe* and *Indian Corn* as illustrations. Some have asserted that the *Potatoe* will yield best by planting only the *sprouts*; some, that the *eyes*, with a small portion of the substance, yield most; some, that the small and refuse are equally productive; while others very rationally and truly contend that the largest and best produce the greatest crop. There is, also, the same diversity of opinion respecting the soil and season, and the manner of their cultivation. And all this, we are confidently told, is the result of experiment. There is the same discordance of sentiment respecting the culture of *Indian Corn*. While on the subject of the *Potatoe*, it may be worthy of remark, that it possesses one peculiarity distinct from any other germinating vegetable. It is not susceptible of vegetation until the season succeeding its growth. From this fact it seems obvious, that nature has not accomplished its maturation at the period when the vines decay, and the farmer believes it to be ripe. It seems probable that the earth, by some unknown process, perfects its qualities, after it has attained its growth. That potatoes, which have remained the whole season in the earth, are more farinaceous and pleasant has been ascertained. A farmer, in this

town, who was in the practice of planting a large quantity, took his family supply from a spacious field, early in Autumn. As the residue were intended for his stock, he deferred harvesting them until a late and more convenient period. During their consumption, his table, by mistake, was furnished with some which had been destined for the barn. The quality was so obviously superior, as to lead to an investigation of the cause. From that time, the two parcels received an exchange of destination.—Another fact, illustrative of this position, was stated to me by an eminent farmer in the vicinity of Boston. A distinguished agriculturist, from Scotland, who had dined at the best tables in the city and its neighborhood, remarked, at the hospitable board of my informant, that he had not seen, in this country, what, in Scotland, would be considered a good potatoe. He imputed their difference to the different mode of cultivation. There, they plant early, and dig late.—Surely the science of Agriculture must be in its infancy, when the cultivation of our most common and staple vegetables is in dispute.

Under such an aspect of the embarrassments of Agriculture, and its tardy progress in this Commonwealth, the Massachusetts Agricultural Society was founded. We are indebted to our metropolis, and its vicinity, for most of the benevolent societies which have been established. This institution is pre-eminently the most disinterested and patriotic. *Merchants* associate for the benefit of trade—*Mechanics*, for the perfection of their art—*Professional men*, for the interest of their callings; but here they all combine to dignify, meliorate, and keep the record of an occupation for the interest of a distinct portion of the community. The fruits of their beneficence are as manifest as are those of the bounteous earth which they have conciliated, and as diffusive as the sun which warms and invigorates it. Without such a stimulus, Agriculture might have plodded on its cheerless track for half a century, without reaching its present eminence. The diffusion of knowledge, and the reward of successful enterprize, are not the chief benefits of this Association. The personal respectability and influence of its founders, and the members who now compose it, have raised this degraded calling to its legitimate standing. Wealth, science, and dignity have become its tributaries; and there is scarcely a man in the Commonwealth, who has an acre of land, and values his standing, who has not ambition enough to be thought a farmer. The benefits of this alliance of wealth and talents are immense to the farmer of limited resources.—Instead of wasting his time and his money in obtaining uncertain results, he has now but to consult the documents of science, furnished by opulence, as his guide.

Since the buiness of farming has become thus honorable, and unites in its service more of mental energy with bodily labor, may we not hope, that by its fascinating blandishments, or solid charms, it will allure votaries from those who seem in danger of mistaking the calling for which nature designed them? Lawyers and Physicians might, perhaps, decimate their number, and improve their breed: and may not some others be added who substitute the labor of the lungs for the labor of the hands—not because it is easier work, but from an impression

that a stock of piety would deteriorate on a farm?

In the rapid progress of our country in improvements, the science of Husbandry now holds a prominent rank. Under our improved management, each acre of cultivated land has doubled its produce to the farmer, with a diminution of his labor. While this adds wealth, it adds also resource to our country. This surplus produce enables her to increase her population, and to support her valuable and increasing manufactures, a prime agent of her prosperity and independence, without extending her possessions; for her land will be better cultivated in proportion to the number it sustains. But the policy of our government seems like that of him who purchased more land to prevent others from bounding on him. Our vast extension of territory may have been wise and politic but it is at least questionable whether the wealth and physical strength of the country would not have been greater, if the wild beasts and savages, the native occupants, had kept possession until a more dense population should render emigration necessary. A wise farmer, though abounding in land, will cultivate no more than he can superintend and profitably manage; but our nation seems to have adopted the policy of those who spend their scanty manure and labor on a large surface, and get little in return.

It is remarked, that in all countries where Agriculture is the chief business of the people, are found the greatest simplicity of manners, more purity of morals, and the best display of the social virtues. By an attachment to the soil, the natural result of its culture, they become the best soldiers, and the firmest patriots. The mere *Merchant*, *Mechanic* and *Professional Gentleman* may be a good citizen, and cherish the ties which are natural to the country which gave him birth, and gives him bread; but, as he cultivates no land, he cannot feel that attachment to the soil peculiar to those who reap the fruits of their own labor. As he can quit his country, when in danger, with more facility, he will not be likely to cherish that deep solicitude for its welfare which the farmer feels, who considers his all at stake. Our statutes seem to recognize this fact. To be eligible to any important office in the Commonwealth, a *frechold* is the first requisite.

To possess a rugged soil, and to cultivate it with sedulous labor, as man is now constituted, is productive of happiness rather than misery to his race. In proof of this position, we need but advert to the condition of those countries where the soil and climate furnish the necessities and luxuries of life, with little labor of the inhabitants. We there find profligacy, effeminacy, and dissipation abounding in the same ratio with the facility of acquiring subsistence. Without intending any invidious distinction, let me ask whether we need look beyond our own country for evidence of the effect of soil and climate upon the moral habits of a people? Was it not from a consideration of this influence, that the discreet Washington selected his confidential soldiers in war, and his domestics in peace, from the most rugged portion of the States? Instead of arrogating to ourselves any superior merit, from the operation of a physical cause, we have only to be grateful, that our lot has fallen where a salutary check is imposed

upon the propensities common to our race.

As Agriculture in an extensive sense embraces all the remote concerns of the Farmer, the object of *public roads* may not be thought unapplicable. Under this head our improvements have been astonishingly great. In the state of our country, while the inhabitants migrated merely for subsistence, it was natural that they should locate themselves with a view only to profit and convenience. The business of intersecting a wilderness in squares and angles, with the skill and regularity of a garden was reserved for the modern display of wealth, speculation and taste. Our new towns have respect to accommodation in the future growth and extension of our country; while the old carry the lineaments which marked the ships of their origin. From a spirit of improvement and enterprize, these traces are worn away as fast as the public convenience can require. New roads are laid out in direct courses through our principal towns; and while the traveller finds his journey shortened, he finds it easy and pleasant, from their excellence. To an agricultural country, no improvement can be more important; for, if the vicinity of a place is to be computed by the distance to be travelled, and the time and labor required in reaching it, the farmer finds himself at one quarter part nearer a market than formerly. If, for this important saving, there has been exciting cause, other than the general spirit of enterprize, to what can it be more justly ascribed than to the introduction of Turnpike. So far from their having caused the decay of old roads, as was predicted in our Senate, an objection to the grant of a charter for the first Massachusetts Turnpike, they have induced such improvement, and excited such spirit of rivalry, that our old roads are not frequently the best.

A new market for the farmer, and new facilities for reaching it are in contemplation, by a *Canal* from this town to Providence. It is confidently believed that a present profit and vast future advantage will accrue to the proprietors and to the community, by the completion of such an enterprize; and it cannot be doubted that public spirit will unite with private interest in so noble and useful an undertaking.

The goodness of a road is the first consideration with the traveller; but its ornament in some measure, serve to lessen a tedious tance. Trees, judiciously chosen, and tastefully arranged, not only delight the senses by their beauty and their soothing shade, but excite a pleasing reflection that they may become substantially useful in some future emergency. Who that has noticed the extensive and narrow rows, which ornament a pleasant village, the place of his nativity and youth, has not felt the force of this sentiment? And who that has seen them would believe, that within a few years these gigantic elms were saplings of the forest, taken from the earth, and transplanted by two boys? I trust it will not be imputed to mere idle vanity, should I add, that, through life, I have contemplated, with great satisfaction, my agency in this early act—not of producing “two blades of grass,” but in adding more substantial beauty and value to my country, and in the consideration, that future generations in contemplating their grandeur, in the enjoyment of their shade, will bless the unknown

that planted them. It gives me pleasure to see that two young gentlemen have evinced like public spirit by adding, in like manner, to the comfort and ornament of Worcester. We not hope this spirit will be cultivated and diffused, until the highway through our country shall appear one beautiful and fertile vale?

selecting trees for public roads, their use as well as beauty should be considered. In this the mazard cherry, the ash, the maple, the elm will be preferred. In cultivating whether for fruit or shade, the farmer is too apt to abandon his business at its commencement.

Having begun a good work, he ought to carry it on to perfection. To replace the dead, to cure the diseased, to prune the too luxuriant, and to protect the whole, is a duty imperative from the pledge bestowed in labor of first planting them. The growth of trees will avail us little, should this be our principal concern. They have roots from without as well as from within: the most formidable is the caterpillar, which, in several years past has made great depredations, and seems now to enjoy an unmolested career.

Does it not argue great imperfection in character as farmers, that reptiles so loathsome and injurious, and so easily destroyed in an early stage, should be suffered to hold year to year, such quiet possession of our valuable trees? A foreigner, in passing through our country, and noticing their condition, which remain inviolate from our untimely touch, would be led to imagine we had adopted the idolatry of Egypt, and instead of the ichneumon and crocodile, had substituted the caterpillar. Even if they harmless, it would be a reproach to us to suffer the beauty of his trees to be defaced.

And fences upon the highways are not only a necessity, but add an ornament to the country. The want of our inclosures, as well as on the edges of our fields and mowing grounds, bushes and weeds should not be suffered to mar the beauty of our roads, or injure the produce of our farms. But how common is it, to see fields and highways laden with a crop, and left to rot on the soil, or washed upon the adjacent ground? If dock and other noxious weeds are not suffered to ripen, they would soon be destroyed. The chaff from our barns would afford pure seed for our fields and pastures, at little expense for the purchase.

We are aware, that the ardor with which we pursue the improvement of our farms and stock has entrenched not a little upon our family, and our domestic regards. A friend stumbling through our enclosure, to witness the growth of our Ruta Baga or Mangel Wortzel, or the tenants of our barns and sties being admitted to our parlors, to an interview with our wives and children, is in the purview of the concerns of the farmer, the health and management of his children embraced, inasmuch as his business requires more of the immediate and uninterrupted attention of a robust family—I avail myself of an occasion to offer a few remarks upon a subject of our general duty.

Inspecting the bills of mortality, it is found that a great proportion of our race are cut off in infancy and childhood. Is this the necessary

state of our existence? Has our wise Creator left the noblest of his work to perish, before the intellect, which is his image, has expanded to contemplate his goodness, and to adore his perfections? Has he bestowed on the brute creation better organs and powers for existence, and rendered *instinct* superior to *reason* in rearing their young? The supposition is both impious and absurd.

Man is the enemy of his race. He is the only created being endowed with reason and the power of reflection, and he alone violates the dictates of nature in the management of his offspring.

The wants of the infant, at its introduction into life, like those of the brute creation, are merely *animal*.—Nourishment and rest comprise the first demands of nature. To the indiscreet management of children, as respects the kind and quantity of their food, is, in a great measure, to be ascribed their sickly frames, and premature death. In early infancy they are commonly gorged to repletion. If kind nature interferes to throw off the offending surplus, it is interpreted into an indication that too much acid of the stomach has contaminated the food. Instead of more caution, and a little abstinence, recourse is had to medicine to correct and remedy what does not exist. By the repetition of his error, and the means to counteract it, the tender organs of the stomach are deranged. By debility, the necessary consequences of distension, it soon becomes irritable, and unfit to retain and digest what, otherwise, would conduce to health and growth. Acridimony is now in fact generated: the first passages are disordered and cholera morbus or dysentery ensues. If the child survives infancy, the same indiscreet course awaits it. Instead of a simple and nutritious diet, in restricted measure, it surfeits on every thing it can see, which a vitiated appetite can crave. Its restlessness and flushes are ascribed to teething; and its cries and starts, to worms. Some injudicious application is made: it dies in fits, or a fever terminates its life. By *rest*, the other primary requirement of nature, I mean still and quiet repose. The cradle has so long been considered such an essential, if not the first requisite in house-keeping, that I may be thought to have entered my second childhood, by denouncing it. But I venture to assert that its use is unnatural, and that it is not found a *labour saving machine*. Nature requires total, unbroken rest.—That use is second nature, is very strikingly exemplified by the introduction of this appendage to the nursery. The infant is not only learned to sleep by unnatural motion, but, in process of time, will not sleep without; and instead of stillness, may be made to require a serenade in the vociferous lullaby of the nurse. It must now be incessantly watched. If it stirs, it is the business of some one to “give the cradle a jog.” By the ordinary noise and business of the family, its nap is rendered short and interrupted: it awakes fretful: it must be caressed and nursed until it again falls asleep: when, on tiptoe, it is again deposited in the cradle, to be watched and jogged. This is trouble enough, but it is only the beginning of it. The child has been so accustomed to rocking and singing, that the mother must spend a restless night, in bed, applying some substitute, or enduring its cries. I say nothing of the luckless father, who, fatigued by the labour of the day, is urged from his perturbed slumber by his now impatient

mate; and, in groping for a candle or a cradle, comes in contact with some angle or projection of this ever protruding furniture; and, in his agony, execrates the cradle and all its concerns, and is half tempted to wish himself *the worst of all wishes*, that he had remained a *BACHELOR*!

Having banished the cradle, the ladies will require me to furnish a substitute. A pillow, securely placed in a darkened room—or a bed, is all that is required. Begin early with the business. Let not the infant be hushed to rest in the nurse's arms. At the fit season for sleep, deposit it in the place prepared, and leave it to itself,—should it cry, as it may at first, let not maternal fondness lead you to its side. The struggle, I know, will be hard to a fond mother; but her discretion will induce her to persevere. A few repetitions of the task, and it will become as pleasant as any other endearing service. One week's discipline of mother and child, will lessen, by at least one half, the trouble of rearing our offspring. I have witnessed this process and its effect in two families, by the most tender, but resolute mothers. Their children in infancy, were of little more trouble to them, than at an advanced period. When they ceased to require sleep in the day-time, they were conveyed to their remote apartment, by daylight or in the dark, to them no matter which, and laid by for the night. By this course, the period as well as the cares of infancy and childhood are abridged, and the energies and mental powers of youth and manhood are more early developed.

But I am admonished that more interesting services await us.

It is a subject of gratulation, Gentlemen, that since our last anniversary, the Legislature, with a foresight and liberality which evince their care for the best interests of the Commonwealth, have extended their bounty for the encouragement of Agriculture and Manufactures, to another period of five years. This patronage, we trust, is in approbation of the measures we have taken for the improvement of these branches of national prosperity and independence, as well as in aid of our further exertions. The specimens of skill, industry, and enterprize, which our Manufacturers exhibit—the produce of the dairy—and the noble animals from our farms—but, more than all, the congregation of so many of our most respectable and substantial yeomanry, whose deportment gives credit and character to the day, afford a demonstration that our zeal has not declined.

And the variety of animals exhibited, it will be noticed that the noblest is excluded. The Trustees have been governed by the consideration that the breed of Horses common in New-England, taking into the account the expense of rearing and keeping, and the qualities for labour on our rugged soil, is the best that can be introduced. In addition to this, it is believed that the interest of the farmer is promoted by substituting the Ox for the Horse, for most purposes, as he is fed with less expense, is more patient of labour, and more valuable when this service is ended.

If *rearing* is essential to the improvement of his breed, we may congratulate ourselves that this noble animal has no part assigned in our exhibition. If the cruel service imposed for the mere purpose of speculation and amusement, we may be more grateful that we have no feelings

which would accord with his unnecessary suffering. The moral sense is improved or vitiated by degrees. Those who are delighted with this sport, may soon attain a relish for more cruel amusement. A late *horse-race*, at Long-Island, was succeeded by a *bull-bait*, in New-York.—Some editors, who crowded their columns with animated descriptions of the one, were scandalized at the toleration of the other. In regard to amusement, it may not be so refined and fashionable; but, in point of benefit, there is no difference. A mere race-horse is, in himself, a useless animal: he has no quality that can be advantageously transferred. A bull-bait may, with as much propriety, be patronized, under the imposing plea of benefitting the race of cows; or cock-fighting, for increasing the size of hens, as horse-racing for the improvement of the breed of horses. As to cruelty, what matters it to the bleeding animal, whether his sufferings are inflicted by the *lash and spur* of a *Parby*, or the *teeth of a bull-dog*?

The exhibitions we have assembled to witness and patronize, have no demoralizing tendency; but are productive of rational pleasure and practical good. Our *trial of speed and bottom* calls forth the power of strength and skill to perform the indispensable labours of life. The pittance of a premium for excellence, is not given or received as a *reward of victory*; but as a badge of honor to him, who, in the cause we patronize, adds most to the benefit of his country. Our display of the improved productions of the earth, and of man, and of the *firstlings of our flocks*, is not made, we trust in the spirit of ostentation—but as a grateful offering to our bountiful benefactor, who has given us the good land we possess, and the blessings we enjoy.

From the Cook's Oracle.

BOILING.

[Concluded from page 142.]

For those who choose their Food thoroughly cooked, which all will who have any regard for their Stomachs, twenty minutes to a pound will not be found too much for *gentle simmering* by the side of the fire; allowing more or less time, according to the *thickness of the Joint*, and the *coldness of the Weather*; always remembering the *slower it boils the better*.

Without some practice it is difficult to teach any art; and Cooks seem to suppose, they must be right, if they put meat into a pot, and set it over the fire for a certain time,—making no allowance, whether it simmers without a bubble, or boils a gallop.

Fresh-killed Meat will take much longer time boiling than that which has been kept till it is what the butchers call *ripe*,—and longer in cold than in warm weather; if it be *frozen* it must be thawed before boiling as before roasting;—if it be *fresh killed it will be tough and hard, if you stew it ever so long, and ever so gently*. In cold weather, the night before the day you dress it, bring it into a place of which the temperature is not less than 45 degrees of Fahrenheit's thermometer.

The size of the *BOILING POTS* should be adapted to what they are to contain: the larger the Stuccan, the more room it takes up on the fire, and a larger quantity of Water requires proportionate increase of Fire to boil it.

In Small Families, we recommend BLOCK

TIN saucapans, &c. as lightest and safest;—if proper care is taken of them, and they are well dried and properly dried after they are cleaned, they are by far the cheapest; the purchase of a new Tin saucapan being little more than the expense of tinning a Copper one.

Take care that the Covers of your boiling pots fit close, not only to prevent unnecessary evaporation of the water, but that the smoke may not insinuate itself under the edge of the lid, and give the meat a bad taste.

If you let meat or poultry remain in the water after it is done enough, it will become sodden and lose its flavor.

Beef and Mutton a little *under-done* (especially very large joints, which will make the better Hash or Broil) is not a great fault; by some people it is preferred; but *Lamb, Pork, and Veal*, are uneatable if not thoroughly boiled—but do not *over-do* them.

A Trivet, or Fish dainer put on the bottom of the boiling Pot, raising the contents about an inch and a half from the bottom, will prevent that side of the meat which comes next the bottom from being done too much,—and the lower part of the meat will be as delicately done as the other part; and this will enable you to take out the contents of the Pot without sticking a fork &c. into it. If you have not a trivet, use four Skewers, or a Soup plate laid the wrong side upwards.

Take care of the Liquor you have boiled Poultry or Meat in; in Five Minutes you may make it into excellent Soup.

The good Housewife never boils a Joint without converting the *Broth* into some sort of Soup. If the Liquor be too salt, only use half the quantity, and the rest water; wash Salted meat well with cold water before you put it into the boiler.

From the New-York Statesman.

NATIONAL INDUSTRY.

The following correspondence between Mr. McGaw, agent of the large printing and dyeing establishment of Messrs. Barrets, Tileston & Co. at Staten Island, and Mr. Clinton, was handed to us this morning, and we take pleasure in laying it before our readers. This establishment is yet in its infancy; but promises to be of great importance to the country. Already, immense quantities of silk, damaged in exportation, and formerly useless to the merchant, are now readily restored to their original colours, and manufactured into handkerchiefs for home consumption or foreign exportation:

Hon. DE WITT CLINTON—

Permit me, Sir, in behalf of the "New-York Dying and Printing Establishment," to testify their respect and gratitude for your successful exertions in internal improvement, and the warm interest you feel in American manufactures, by presenting to you a few vest patterns, printed at their Establishment, and for which the premium was awarded at the late annual fair in this city. It is from distinguished statesmen like yourself, who correctly appreciate whatever contributes to the glory and independence of a nation, that native genius and native skill expect encouragement and protection.

To Mrs. Clinton they beg leave to present a few yards of printed muslin, exclusively of American manufacture, printed at the same place, and for which the premium was also awarded,

and which is the first piece of that style of work ever executed in America.

These specimens are not presented for their intrinsic value, but merely as a tribute from a department of our home manufactures, to a distinguished citizen, who has done so much to patronize domestic industry, in connexion with the other leading interests of our state and nation. With sentiments of the highest respect,

I am, Sir, Your Obedt Servt,

ISAAC M-GAW.

New-York, Nov. 13, 1823.

(COPY OF THE ANSWER.)

SIR—The elegant fabrics of American manufacture presented by the New-York Dying & Printing establishment, through you, have been highly gratifying to me, as evidence of the genius of our manufacturers, and of the good opinion of the members of an excellent institution, which has greatly contributed to elevate the character and extend the usefulness of important branch of productive industry.

I have always considered it the incumbent duty of our citizens and our government to encourage our own manufactures—which must all times be deemed a great interest that recovers the benefits it receives, and acts as the most propitious influence on the primary sources of national prosperity, using enhancing the products of the soil, and at the same time creating the means, administer the demands, and exciting the energies of commerce; I feel pleased, therefore, to understand that you duly appreciate my views on this subject; and I pray you to present my respectful acknowledgments to the respectable association which you represent, and to accept my sincere thanks for the kind and courteous manner which you have expressed yourself in my behalf. I am, Sir, with great respect,

Your most obedient servant,

DE WITT CLINTON.

Isaac McGaw, Esq.

From the Free Press.

We have been politely furnished by the Hon. J. BAYLES, with the following extracts from his Address before the Bristol County Agricultural Society, where we take great pleasure in presenting to our readers.

"It is now but little more than two hundred years since our soil was first imprinted by the footsteps of a white man.

"Some of the trees which formed a part of the primeval forest are still remaining; their limbs are still defying the blasts of winter, a the storms of autumn; still towering in the pride of their strength, unimpaired by the assaults of time, and surviving the destruction of nations.

"The wild race which once sheltered in the shades have disappeared, the places which they knew them, now know them no more. The posterity of the humble and wandering pilgrim who succeeded them have swelled into a nation, and yet, the trees remain; human law and human customs, language, government, philosophy and the arts may, and do change, but nature continues her certain though silent progress, for her laws are eternal and immutable.

"In the year 1621, Edward Winslow traversed this region on his first journey to the savage chief, who ruled this then savage domain, at the seat of whose dominion was at Montauk.

low Bristol) from Tittiquet to Swansey he discovered but two nations, and no settlements.—though the ground was cleared on each bank of the river, yet the melancholy silence of desolation was uninterrupted save by the cries of wild beasts, who were prowling for prey through the horrid solitude of this wilderness. The wolf made his den within sight of his house. The startled deer swept along the common, and wild Turkeys winged their flight near the Temples of the true God are now elevating their spires to the heavens.

"A few scattering savages served to tell that man was here, and a few patches of maize served to show the amount of his labors.

"A tribe of savages in number less than three thousand occupied a part of Rhode Island and the whole ancient colony of Plymouth, gathering a wretched subsistence, and frequently perishing, the miserable victims of famine, where more than 150,000 civilized beings are now supported in ease and in plenty.

"It is the skillful application of labor to the soil, it is the science of Agriculture, it is superior knowledge in the art of cultivating the earth, which has thus multiplied its capabilities.

"By constant watches against the depredations of wild beasts, the aborigines strove to cultivate in small quantities a single species of squash and pumpkin; kidney beans and maize or Indian corn. On the borders of the fresh water streams grew a species of coarse grass, more worthless species covered some of the largest plains, and in the vicinity of salt water, the marsh grass, then, as now, grew in rank luxuriance. Wild cherries, raspberries, wild grapes, strawberries, boxberries, blackberries, and huckleberries were the only native fruits.

"The hog, the sheep, the horse and all the beasts of draught were unknown. All other grains, grass, vegetables, roots, plants and all other domestic animals have been introduced from other countries.

"The original species of forest wood still remains, but few exotics have been introduced, and some of those might have been spared.

"The agricultural riches of different regions have been diffused and made common by the operations of war, commerce and emigration.—The love of the agricultural art has diffused its movements, and its curiosities, rather than the more important objects of its culture.

"The ferocious soldiers, and bigoted fanatics of Spain have given to the world a treasure rather than the philosopher's stone or the elixir of immortality, by transferring the wild potato from the region of the River La Plata and the mountains of Chili to Europe. By this the world has been saved forever from the desolations of famine. The goodness of God is manifested in every thing. The same hands which destroyed human life without measure, and without mercy, have given to countless millions the means of living; and by introducing the precious bark of Peru into medicine have driven from the earth a desolating scourge which destroyed more victims than the plague, or yellow fever.

"It is not by partial introduction of fine animals from other countries, a solitary bull, or horse, or sheep, or swine of a single species, but from the introduction of all the valuable breeds from every country, that the great objects of obtain-

ing the most perfect of every breed can be attained. To effect this, the institution of societies like ours is peculiarly favorable.

"Whenever our funds are sufficient to authorize the expense of the importation, every variety of valuable foreign animals, ought to be introduced here, particularly of *beef cattle*. I will venture to assert that our boundless empire contains no soil and no climate more congenial to the production of fine beef than the necks of Swansey and Somerset, that part of Troy which lies on the river, the parts of Dorchester and Westport which are situated on the sea, and the adjoining part of the state of Rhode Island, including all the islands in Narragansett Bay.

"It is in your power to exhibit beef unequalled in Leadenhall market, and surpassing the *Magnus* and *Maximus* of *Connecticut river*.

"I trust you will excuse me, if I briefly advert to a circumstance which in some places has threatened to destroy the harmony which ought to exist between two great national interests, for whose equal encouragement our society was instituted. An attempt has been made to excite a jealousy between the manufacturers and the farmers by representing their interests as hostile and incompatible, and that the prosperity of the one was necessarily injurious to the other.

"A position more false than this could not have been assumed. Before the extension of the manufacturing system, agriculture flourished from the operations of commerce, but the world was in a situation novel and peculiar, there was a general war amongst the nations (with the exception of ours) a war which required vast armies: To supply them the agricultural productions of America were sought because America being neutral could carry safely, and sell cheap.

"The military force of the West Indies also drew their supplies from the states. The war having terminated, this lucrative commerce is at an end. Every European nation can supply more of the productions of agriculture than are necessary for the subsistence of their population, and of course there must every where be a surplus which cannot be used. Great Britain who is possessed of more colonies than any other nation, by some late regulations has endeavored to supply the wants of one colony with the productions of another. Wheat, rye and potatoes have been imported into this country from others, and it is now an undeniable fact, that the surplus productions of New-England cannot be sold in foreign markets without loss.

"But if a certain and convenient domestic market can be created, the farmer loses nothing by the failure of foreign markets, which would be necessarily uncertain and fluctuating, but domestic markets, would be steady, and the demand would be constant.

"The benefits of the domestic market may be familiarly illustrated. A family is withdrawn from agriculture, and employed in manufacturing, which family must be fed and supported. A farmer in the neighborhood, can raise a sufficiency from his farm to supply his own family, and surplus enough to support the other. The family employed in the steady labor of a manufactory cannot cultivate the earth, and their wants are supplied with the surplus of him who does, which otherwise might have been unsold, and both are benefited.

"If one hundred families are employed in a

manufactory, one hundred farmers are sure of a market.

"A manufacturing population rear up cities and villages, lands of course become more valuable, more saleable, and more productive. A manufacturing population must be fed by agricultural population; of course agricultural labour becomes more productive. The land is better cultivated, its hidden capacities are developed, and the manufacturing village is soon surrounded by a continuous garden. Both classes are daily adding to their own wealth, as well as to the aggregate wealth of the nation.

"Examine the history of the world and you will invariably find that the progress of agriculture has been by far the most rapid in those nations which have fostered the other great branches of national industry. Therefore let no unworthy jealousies exist between the farmer and the manufacturer. They are mutual aids to each other. It is for the interest of both classes that both should flourish."

From the New York Statesman.

Natural History.—We are indebted to a correspondent and friend for a copy of a Discourse on the *Utility of Natural History*,—delivered before the Berkshire Medical Institution at the organization of the Lyceum in Pittsfield, Massachusetts, on the 10th of September last: by the Rev. Edward Hitchcock, of Conway. The author of this pamphlet has brought much talent, much learning, and much good sense to the illustration of his subject. He appears to be well versed not only in his own profession, but in that of medicine, and in the several branches of natural history. From his view and citations, it is evident he is a gentleman of extensive reading. To the question so often asked—of what use are the pursuits of natural science? he has given very full and satisfactory answers. This address is arranged under three general divisions: first, the utility of natural history in relation to the common and social interests of man; secondly, its utility in relation to intellectual improvement; and thirdly, its religious influence on the mind. Under these several heads, he has advanced a great variety of arguments and enforced them with no ordinary share of eloquence, combined with taste and piety. His speculations on the various geological theories are both learned and rational, defending the Mosaic account of the creation and of the deluge.

At the conclusion of the discourse, several gentlemen from Berkshire and the adjoining counties, formed a society under the name of the Lyceum of Natural History of the Berkshire Medical Institution, and adopted a constitution. At a subsequent meeting of the members, Chester Dewey, A. A. S. was elected President; D. Hunt, M. D. Rev. Edward Hitchcock, and J. P. Batchelder, M. D. Vice Presidents; Henry H. Childs, M. D. and Dr. O. Wright, Curators; Henry K. Strong, Secretary, and Samuel M. McKay, Treasurer.

The Lyceum have already received several boxes of minerals, shells, Indian implements, and animals, from different parts of the country, and a respectable cabinet is collected in the infancy of the association. Considerable additions are expected from a class of about eighty medical students, now attending a course of lectures

at the institution with which the Lyceum was connected. The members respectfully solicit the aid of gentlemen in increasing their cabinet of curiosities. This society appears to have commenced under favorable auspices, and will doubtless become extensively useful in the cultivation and diffusion of natural science.

Human Life.—According to accurate tables kept in London, it appears that the mean duration of the life of Man is several years longer than it was 100 years ago. It was said by an eminent physician of our country, that according to the principles of longevity in other animals, men ought to live 100 years; and that the abridgement of that period was owing to their unmanly and luxurious manner of living. —The English calculators attribute the increased longevity of the moderns to better food, warmer clothing, and more comfortable dwellings. No doubt the extermination of the small pox, the amelioration of several other diseases, and the increased skill in the healing art, have also had an effect to produce the gratifying result.

Method of Polishing or Cleaning a Stove.—Take 1-4 lb. Black Lead, mix it with water, then put it on the Stove with a paint brush, and after it is perfectly dry, take a stiff brush to it, which in a few minutes will produce a handsome polish. The above is recommended by our first rate Stove Polishers.—*Boston Gaz.*

Caution.—It will be seen by our record of deaths, that a man died recently in Massachusetts, in consequence of drinking oil of tansy, through mistake. Within a few weeks the lives of two ladies, one in this town and the other in East-Greenwich, were endangered, by their incautiously taking with tansy water some portion of the deleterious oil which floats upon the surface.—*Rhode Island American.*

The Railway (N. J.) Advocate mentions, as a great day's work, that Mr. Isaac Thornall husked, for a bet, between sunrise, and sunset, one hundred and thirty and a half bushels of corn.

NEW ENGLAND FARMER.

SATURDAY, DECEMBER 6, 1833.

Winter Butter.—If milk cows were fed with roots butter might be made during the winter. Some dairy women, however, complain that it is almost impossible to churn their cream into butter in cold weather. Mr. Van Emberg (See N. E. Farmer, vol. ii. p. 124, 125.) directs to keep the milk till it begins to change, and then to churn it. He advises to mix the night's milk with that of the next morning, and "in summer this change generally takes place about ten o'clock; in cold weather it requires to be kept longer for this purpose, say in spring and autumn, the milk of the first mess may be kept till the day following, and then requires the addition of warm water to the milk to bring it to the right temperature for churning." Others advise in cold weather to pour as much boiling water into the cream as will bring it to about the temperature of milk just from the cow. It is said that cream managed in that way will require but very little churning, and is attended with no disadvantage except that the butter will be white a day or two.

It is said in Hunter's Geographical Essays that good but-

ter may be made from cows fed on turnips as follows.

"Let the vessels which receive the milk be kept constantly clean, and well scalded with boiling water. When the milk is brought from the dairy, with every eight quarts mix one quart of boiling water, and then put it up to stand for cream." This it is asserted will destroy the taste of the turnip, and perhaps may facilitate the process of churning.

Dr. Drane's N. England Farmer states that "a strong rancid flavor will be given to the butter if we churn so near the fire as to heat the wood in the winter season. In churning for butter always have an orifice sufficient for the air to have access to the cream. Butter is produced by the union of oxygen with the cream, and more butter will be produced, and of a finer flavor, if the churn is sufficiently open."

It is recommended by some writers to shorten the operation of churning by mixing a little distilled vinegar with the cream in the churn. A table spoonful or two to a gallon of cream is advised, and the acid may be carried off by washing the butter in two or three changes of water.

In Scotland dairy women give their butter a fine yellow color by grating some orange carrots, straining the juice and mixing it with the cream previous to churning. Butter thus made acquires not only a beautiful yellow color, but a flavor which adds greatly to its value. The quantity of carrot juice to be used must be ascertained by experiment and the judgment of the manufacturer.

Although the following mode of curing butter has been published in newspapers and agricultural works, it may be new to some of our readers.

"Take two parts of the best common salt, one part of sugar, and one part of salt petre, beat them up together so as to blend the whole completely: take one ounce of this composition for every sixteen ounces of butter. Mix it thoroughly with the butter, as soon as it has been freed from the milk (which should be done effectually,) and put it without loss of time into the vessels prepared to receive it, pressing it so close as to have no air holes, or any kind of cavities within it;—smooth the surface, and if you expect it will be more than two days before you add more, cover it close up with a piece of clean linen that has been dipped in melted butter, that is exactly fitted to the edges of the vessel all round, so as to exclude the air as much as possible, without the assistance of watery brine.—When more butter is to be added, remove the covering, and let the butter be applied close above the former, pressing it down, and smoothing it as before, and so on till the vessel is full. When full, let the two covers be spread over it with the greatest care, and let a little melted butter be poured round the edges, so as to fill up every cranny, and effectually exclude the air. A little straw may then be strewn over the whole, and the cover firmly fixed down, to remain closely shut till opened for use.

"Butter cured in this manner, does not taste well till it has stood at least a fortnight after being salted: after that period has elapsed, it eats with a rich marrowy taste that no other butter ever acquires. Butter thus cured will go well to the East or West Indies."

American Manufactured Lead Pipes for Aqueducts.—We have before us some specimens of leaden pipes, manufactured by Mr. David Loring, of Concord, Massachusetts, which are neatly wrought, and have every appearance of being fully equal to any leaden pipe imported from England. These pipes are of vari-

ous sizes, and we are informed are afforded at a cheaper rate than those of a similar quality manufactured in Great Britain. Pipe of a diameter sufficient for supplying water for a common family, including what would be necessary for a barn yard, well stocked with cattle, is furnished, and placed in the ground, (after the ditch is dug) for \$1, 25 a rod, which is cheaper, we are told, than wooden pipes can be bored and laid. The duration of these pipes has no assignable limits, as they are not liable to rust or decay in the ground; and are warranted to withstand the pressure of the earth and water.

Specimens of this pipe, of different diameters, with the different prices marked on them, are left at the Agricultural Warehouse of Lincoln, Fearing & Co., No. 20, Merchants' Row, Boston; where they may be inspected by any persons who may wish for further information on this subject.

Rapid Growth of a Strine.—A friend writes to us that he "sold a pig last spring, which was slaughtered seven months after the sale, and had gained one pound and one third a day, without making any allowance for his being weighed, in the first instance, when alive, and killed and dressed when he was weighed last."

FOR THE NEW ENGLAND FARMER.

MR. EDITOR,

Sir,—I noticed in your paper of the 15th inst. a communication from "J. Subacber," on the subject of cutting hay and straw. As the communication appears to be made from disinterested motives, I hope it will excite the attention, which it merits, not only from our wealthy farmers, but from those to whom it would be of the utmost consequence in point of economy. I have been long in the habit of cutting not only straw, but common hay and cornstalks, and have experienced the good effects in the appearance of my stock; and have proved beyond a doubt that the greatest saving may be made in this mode of expending fodder. The present season is a favorable time for those unacquainted with the profit and advantage to be derived from this mode of feeding. Although hay may not be scarce, nor uncommonly dear, yet it is not so abundant as we frequently have had it for seasons past. From this circumstance, I think many farmers may be induced to try the experiment, which if fairly tested would never be abandoned.

One great and principal reason, which I have often heard assigned by many of my neighbors for not adopting this practice is the hard labor it occasions, and the want of a suitable machine for the purpose. To remove these objections, I will take the liberty to recommend a new and useful machine, now manufactured, and for sale at the Agricultural Establishment, (so called,) in Merchants' Row. This machine appears to combine every qualification necessary to remove the objectionable points. It does not require hard labor; is not an expensive machine, is simple and plain in its construction, easy in its operation, and every way well calculated for hand labor.

FOREIGN.

Spain.—The last accounts from that unhappy country are, as usual, confused and contradictory. Some reports represent the country as still in a state of agitation; and that the constitutional leaders still keep the field. A private letter from Bayonne of the 14th ult. states that "the impulse has been given by Ballesteros, who is with a respectable force in the neighbouring mountains. The cry in all that country is 'the Constitution or death,' and they wear the green ribband. Jaen is not tranquil. The desertion is considerable, and the prisoners of Riego's corps escape as if by a miracle from prison." It is also said that the proclamation of the King, declaring all the acts of the Constitutional Government null and void including all the loans made by that government, continues to create much excitement among the capitalists, who have been dealing in Spanish Bonds. It is rumoured that France, Spain and Portugal intend to join their efforts to restore

PARAMOUNT PUNNING:—OR SETTING UP,
AND SITTING DOWN.

A chap once told St. Patrick's Dean,
While rising from his seat, "I mean

To sit up for a wit."

"Ah!" quoth the Dean, "If that be true,

The very best thing you can do
Is down again to sit."

Too many, like that would-be wit,
Set up for what they are not fit,
And always lose their aim;—
Set up for wisdom, wealth, renown,
But end the farce by sitting down,
With poverty and shame.

A middling farmer thinks he can
Set up to be a gentleman

And then sit down content;
But after many a turn and twist
Is set down on the pauper list,
A fool, not worth a cent!

When farmers' wives and daughters fair
Set up with silks and Leghorns rare,
To look most wondrous winning,
They set upon a slippery stand,
Till indigence, with iron hand,
Upsets their underpinning.

Some city ladies too, whose gear,
Has made them to their husbands dear,
Set up to lead the ton;
Though they sit high on fashion's seat,
Age, death or poverty, albeit
Will set them down anon.

Some fools set up to live by law,
And though they are "all over jaw,"
Soon fail for lack of brains;
But had the booties only just
Known where they ought to sit at first,
They'd sav'd a world of pains.

A quack sets up the doctor's trade,
But could he use the Sexton's spade
No better than his pills,
The man might moil from morn to night
And find his match with all his might
To bury half he kills.

You may set up for what you choose
As easily as wear old shoes,
If e'er so low at present;
But when you have set up in vain,
And find you must sit down again,
'Tis terribly unpleasant.

EPITAPH ON A MISER.

Here crumbling lies, beneath this mould,
A man, whose sole delight was gold;
Contentment never was his guest,
Though thrice ten thousand fill'd his chest;
For he, poor man, with all his store,
Died in great want—the want of more.

Mistake Corrected.—In our last paper, page 144, we reprinted from the N. Y. Galaxy, an elegant piece of poetry, entitled "Autumn." But the two following lines which should have preceded the last line of the first verse, were omitted by inadvertence.

"While from wide trees that overhang the lane,
The ripe red apples, shaken down at dawn."

Those lines inserted, the stanza would read as follows:

How dear to roam along the sunny hills,
When autumn spreads her bounties o'er the plain;
When industry his garner'd treasure fills
With richest stores from fields of ripen'd grain,
When slow across the glebe the ponderous wain,
Deep laden with the yellow ears is drawn;
While from wide trees that overhang the lane,
The ripe red apples, shaken down at dawn,
Lie scatter'd thick and far along the level lawn.

Though we plead guilty to the accusation of having mutilated this passage, we can assure the author there was no *malice prepense* in the matter, and we should be happy to atone for our error by printing correctly some future productions of his muse.

MISCELLANY.

ANECDOTES.

Original Anecdote.—A peculiarity generally attributed to the yankees, is that of answering a question by asking another; and numerous anecdotes are related to prove that it exclusively belongs to them. But whoever has travelled south must have noticed that it is quite as common among our southern brethren—whom by the way Europeans call yankees—as it is at home in New England. That this peculiarity is there, indeed, happily blended with some others, the following anecdote will illustrate.

A gentleman passing through one of our southern states, and wishing to know the distance to a neighboring house, enquired of a Planter, who was leisurely at work by the road side, how far it was to Pierce's. "From up country, I reckon?" "Yes," said the gentleman. "Well, how goes cotton?" "Rather dull, I believe." "Mighty bad roads, friend." "But," says the traveller, "how far do you call it to Pierce's?" "Bound to S.—, I reckon." "Exactly," answered the traveller, and rode on—when the planter, having completed his enquiries, proceeded to reply, "Well, now I don't jestly know exactly, how far, but I reckon you'll find it something of a piece before you get there!"—*Portland Advertiser.*

The Hard Case.—A physician of Dublin being summoned to a vestry, in order to reprimand the sexton for blunders he had committed thro' drunkenness, dwelt so much on the poor fellow's misconduct as to raise his anger, and draw from him a retort: "Upon my soul, sir, this is ill-natured; and that you should be so eager to lay open all my blunders, when I have so often, so very often, covered yours, is hard, very hard, Master Doctor, that's all."

Advantage of Wealth.—A rich upstart, who had obtained a great fortune by means not always consonant with the rules of honor or of honesty, asked a poor but shrewd Irishman if he had any idea of the advantages arising from riches. "I believe," replied the wit, "they often give a rogue an advantage over an honest man."

New Anecdote.—A tin pedlar called upon a spindle shanked old gentleman, in small clothes, and tight silk stockings, and inquired "do you want any tin ware?" It was dog days and the lies had taken a peculiar liking to the old gentleman's legs, calling for the constant employment of his hands to brush them away. "If

you have a pair of tin boots, I should like them, said he pettishly, "O yes," said the pedlar, at running to his cart, returning with a pair, candle moulds, "those sir, will exactly fit you."
[*Albany Argus.*]

Taking Advice.—An avaricious, hypocondriacal gentleman fancied himself to be very much out of health, but being too penurious to pay doctor's fee, thought he would steal an opinion concerning his case. Accordingly, one day, being in familiar conversation with one of the culty, he asked him what he should take for such a complaint. "I'll tell you," said the doctor, "you should take advice."

PRUDENTIAL MAXIMS.

The eye of a master will do more work than his hands; and not to oversee workmen is to leave your purse open.

Trusting too much to other men's care is the ruin of many; for in the affairs of this world men are saved, not by faith but the want of it.

If you would have a faithful servant, and one that you like, serve yourself.

A little neglect may breed great mischief for want of a shoe a horse was lost, and for want of a horse the rider was lost; being overtaken and slain by the enemy, all for want of care about a horse shoe nail.

If you would be wealthy, think of saving as well as of getting. The mines of South America could not make Spain rich, because her outgoes were greater than her incomes.

It often costs more to maintain one vice than to bring up two children.

If goods are sold ever so cheap, and you do not need them, they are too dear for you to purchase; for if you buy what you do not need you may soon have need to sell your necessities.

Sir Edward Hume, has recently made some interesting enquiries, by way of comparison, between the articular organs of man and quadrupeds. The result of his researches seems to prove that shrill tones, or the upper notes of an instrument, have comparatively little effect exciting the attention of animals whilst the lower tones stimulate them almost to fury. Everard observes, "that the effect of the high notes of the piano-forte upon the great lion Exeter Change, only called his attention, while was considerable, though he remained still and motionless. But no sooner were the flat-lower notes sounded, than he sprang up, lashed his tail, and yelled violently, and endeavored to break loose; and became altogether so furious as to alarm the spectators present. This violent excitement ceased with the discontinuance of the music. The deep tones of the French horn so produced a similar effect with the lower tones of the piano-forte, on the elephant, and other animals, on which the experiment was made."

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

Farmer's and Gardener's Remembrance.

[BY THE EDITOR.]

FARMERS' ACCOUNTS.

Perhaps there is nothing of equal importance, which comes within the whole compass of a farmer's concerns, more commonly neglected than the keeping of regular account books. A tradesman, or shopkeeper was to be equally diligent, in that respect; he would be thought fit, far advanced on the road to ruin. An enterprising agriculturist gives some maxims on this subject, which are in substance as follows:

GENERAL ACCOUNT OF STOCK.—Every farmer desires to know correctly to what profit his business, should provide himself with a book, in which he may call his *General Stock Book*. In this book, some time in December, he should register the result of a general survey of condition and worth of his whole stock and property, of his debts and credits. Having such a book to refer to at all times and on all occasions, will afford much satisfaction to his mind. The first place he should order in all his business bills, and in the mean time he may have an examination and account of all his household goods, horses, cattle, poultry, corn, grain, hay or threshed, hay or other fodder, wood, fire, wagons, carts, ploughs and implements of all kinds—the state of his fences, gates, &c. and make an estimate of the necessary repairs. Minutes being made on waste paper, the particulars may be afterwards entered in the *Stock Book*, with such a degree of minuteness as may be judged necessary. After the general register a Dr. and Cr. account may be drawn out, the balance of which will exactly show the present worth of his estate.

The form of the account may be as follows:

Stock Dr.

Contra Cr.

In the Dr. side should be entered all the purchases, and on the Cr. side all the sales, and all that is owing to him. He must be very diligent at what he judges to be the present worth, was it then sold; manure, &c. large performed must be valued at the present rate of the country.

A farmer wishes to be very correct in his calculations of the profit and loss, upon a lot of stock, for instance, or the crop of any particular field, his readiest method is to make an account for either the one or the other in his Dr. and Cr. On the Dr. side let him enter the cost, including every minute particular, and on the Cr. side the returns. On the Cr. side the articles, the account is closed, and the balance demonstrates the profit and loss.

SALTING MEAT.

This is a very important subject to the country farmer. Rusty pork and beef, none of which are good for anything, are about as common as cabbages on apple trees, or weeds among corn. Do not pretend to much experience as respects the preservation of meat; and shall, therefore, say nothing more than quote from good authorities such directions as appear most likely to be beneficial in practice.

Dr. Deane observed that "the common method of preserving pork, reserving the lean parts for use in the cold season, and applying a large quantity of salt to the fat, is perhaps as good as any can be. But beef is greatly injured, and rendered unwholesome by severe salting. A good method of preserving beef, which I have known practised for several years past is as follows: for a barrel of common size, reduce to powder in a mortar four quarts of common salt; then eight ounces of salt petre, and five pounds of brown sugar. Let the salt be well rubbed into the pieces, pack them close in the barrel, and sprinkle the salt petre and sugar evenly over each layer. No water at all is to be applied. The juices of the meat, if well packed, will form a sufficient quantity of brine; and the beef will keep sweet and good through the following summer, supposing it killed and packed in the beginning of winter or late in autumn; and will not be too salt to be palatable. Draining off the brine and purifying it by boiling and scumming, with the addition of a little salt will be a real improvement."

An English publication gives the following as the Russian mode of salting meat:—"Boil over a gentle fire six pounds of common salt, two pounds of powdered loaf sugar, three ounces of salt petre, and three gallons of spring water. Carefully scum it while boiling; and when quite cold, pour it over the meat, every part of which must be covered with the brine. In this pickle, it is said the meat will not only keep for many months, but the hardest and toughest beef will thus be rendered as mellow and tender as the flesh of a young fowl; while either beef, pork, or even mutton will have a fine flavor imparted by it. In warm weather, however, the blood must be expressed from the meat, and the whole well rubbed over with fine salt, before it is immersed in the liquor.—Young pork should not be left longer than three or four days in this pickle, as it will then be quite sufficiently softened; but hams, intended for drying, may remain a fortnight before they are hung up; when they should be rubbed with pollard, and closely covered with paper bags to prevent their being fly blown."

An American writer on this subject, whose remarks, we believe, were first published, some years since in the Connecticut Courant, gives the following directions:

ON KEEPING MEAT.—"There are two points to be considered with respect to meat. The longer it is kept without salt, the tenderer it becomes. If it receive salt in this state it becomes correspondingly tender, and the smaller the quantity of salt, used in its preservation, the looser, sweeter and more palatable will be the meat.

*If in this mode of salting beef, there should not be a sufficiency of brine produced by the juices to cover the beef within five or six weeks, which will sometimes happen, it will be well to make a quantity of brine sufficient for that purpose, and pour it into the barrel; and care should be taken to keep any kind of salted meat, especially in warm weather always below the surface of the brine, by a large stone, or some other weight.

"**BEEF.**—Let it lie in a cool place, without freezing, about a week; use eight ounces pulverized salt petre, and six quarts of fine salt to a barrel—put water to these in a convenient vessel; roll the pieces of beef separately in this; pack them in the cask lightly, and in two or three days fill it up with water. You need not be alarmed if it become a little slippery in the spring, provided it is not tainted. The plate pieces of a fat beef are about as good as tongue, and keep as well as pork.

"**HAM.**—For the same reason, hams improve by lying a week or eight days, if the season admits of it without freezing. For an average for one ham use one ounce of salt petre; or if large two ounces; pulverize it, and with fine salt and water, wet the hams and lay them into a barrel. Prepare immediately a weak pickle, to the taste as salt as the ham is wanted, and after two days cover the ham with it. Six or eight pieces may be smoked in a week, in a common oven. Lay them on sticks of wood;—place some walnut or maple chips within the lid; raise this a little and put some coals to them. The smoke thus produced is much better than the smoke of a common chimney."

The following recipes for preserving meats are recommended by THOMAS COOPER, Esq. Professor of Chemistry and Mineralogy.

For meat intended for family use, and to be used in two or three months, take "water, one gallon; salt, nineteen ounces; salt petre, one ounce and a half; sugar, half a pound.

The Russians are fond of the juice of juniper berries, and add a pound of bruised juniper to a gallon of pickle.

A tea-spoonful or two of Cayenne pepper to the gallon, greatly increases the preserving power of the pickle.

To cure gammons, first sprinkle them as soon as they are cut and trimmed with a little (Liverpool) salt. Let them lie together for twelve hours: take them out of the tub, drain and wipe them; then rub them separately with a mixture of 12 parts common salt and one part salt petre, well dried and then ground fine.—Rub in this mixture well; lay them in the pickling tub, and the next day rub them again with a similar mixture. The day after fill up the tub with a brine made in the proportion of 18 oz. salt, 1 lb. molasses, and 1 oz. salt petre, to the gallon of water. In this pickle they may stay for a fortnight. Then take them out, drain, wipe and smoke them.

If they are suffered to make their own brine by means of dry salt and salt petre, entirely, they will lose too much of the juices of the meat, and become hard and dry.

I have successfully cured beef in summer thus: I killed an ox in the middle of August, at 9 o'clock in the evening; it was cut up at 3 o'clock in the morning. The pieces were quickly rubbed with a mixture of ten parts of salt and one part of salt petre, and put into a barrel. In the mean time a brine composed of 1 1-2 lbs. salt, 2 oz. of salt petre and half an ounce of common pepper, to the gallon of water, was ready over the fire, and when the beef

was all packed in the barrel, it was poured on boiling hot. This prevented and destroyed all fly blows. In a week the pieces were taken out, dried and wiped; the pickle was boiled over again, scummed, and again poured boiling hot on the meat when repacked. The process answered the purpose perfectly."

In Banister's Synopsis of Husbandry we find the following directions for preserving pork, which we believe nearly accords with the practice of the best Economists in this country.

"The fat or prime pork is to be cut into pieces of a size proportioned to the circumference of the powdering tub [or barrel in which the pork is salted] and every piece is to be rubbed on each side, and on every part with common salt having on hand some powdered salt petre to sprinkle on each. Let the bottom of the tub be covered with salt, and when the pork is sufficiently powdered the pieces are to be laid in, with the rind upwards, and every piece to be pressed downwards with all the strength that can be used, and wedged in so very close as to leave no apparent chasms. Over this layer is to be spread a covering of salt with a sprinkling of salt petre. To a hog of twelve score will be required nearly a bushel of salt, and two pounds of salt petre, and so in proportion for those of larger dimensions. In about a month or five weeks the brine will begin to rise, and in a short time afterwards will cover the whole surface of the tub: but if from defect in the salt, it should fail to produce the brine in that period it will be necessary to make a quantity of brine and pour over the pork; for unless the whole be covered with brine the pork will undoubtedly be rusty. But there is this inconvenience attending the latter method, namely, that it is apt to loosen the pork, and cause it to swim, a circumstance which would likewise occasion rust. If, therefore, it should be necessary to pursue this mode of making brine, let a large clean stone be laid on the top of the pork, in order to press it down and prevent it from swimming."

There is no danger of using too much salt in preserving fat pork. The meat will absorb no more than will prove useful, and the remainder will answer for salting a fresh parcel on any future occasion.

* Although Mr. Cooper's observations on this subject were published in the first volume of the New England Farmer, page 37, we thought it best to re-publish it here to render this article more complete, and accommodate those of our readers who may not be in possession of the first volume.

THE WHEEL HOE.

The following is a representation of an implement which is used in the neighborhood of Paris, Brussels, and some other parts of continental Europe. Its principal use is to clean gravel walks in gardens, but it may be applied to scraping the surface, and cutting up and eradicating weeds, &c. from any other smooth soil, where the weeds are not large and strongly rooted. It is worked by two men. One man pulls forward, while the other regulates the hoe, according to the nature and abundance of the weeds to be extirpated. The dispatch thus afforded is great, two men being able to do as much work with this machine as six men could perform in the same time with hand hoes. The

figure, and the substance of this description is copied from a work, printed in Edinburgh, in 1823, entitled "*Journal of a Horticultural Tour, through some parts of Flanders, Holland, and the North of France. By a Deputation of the Canadian Horticultural Society.*"

FOR THE NEW ENGLAND FARMER.

Mr. Editor—Permit me through the medium of your paper, to offer to the public a few observations on the Piscidia or Dog Wood. This tree so well known to almost every farmer, is a genus of the Decandria order, belonging to the diadelphia class of plants. There are several species,—but that we shall notice is the Erythrina, or common Dog Wood. This grows spontaneously in our woods, where it rises to the height of 25 feet or more. The body is covered with a light colored smooth bark, and it sends out several small branches at the top in an irregular manner, with long oval leaves.—This tree emits a peculiar and very disagreeable smell, of an active and poisonous nature.—It is this quality which we shall more minutely describe, since it is so pestiferous to most of the human family, by corroding or poisoning the skin. This effluvia readily turns paper stained with syrap or violets, green, a sure indication of its alkaline nature. The expressed juice of the bark is strongly astringent, precipitating iron from its solution of a black color; but as this astringent property is not pernicious to the animal system, we must conclude the poisonous quality of this tree is in a great measure owing to the alkali which is so very subtle as to insinuate itself into the pores of the skin, and act upon the organized fibre, decomposing the parts affected, and causing innumerable small vesicles to appear, accompanied with insupportable itching. Having described the tree and its effects as a poison, I shall now prescribe an antidote which from my own experience I know to be invaluable; and which also holds good in theory. Acids should be used to counteract the effects of alkalis. Let the person afflicted wash the affected parts in a solution of *sulphate of iron* in water, one ounce of the former to one gill of the latter, as often as 12 or 16 times in the course of a day and a cure will be effected in two days. I would caution the public against using an alkali as a remedy,—for I have seen pearl ash administered more than seven years since, and its application was attended with disagreeable consequences.

I am, Sir, the public's friend and servant,
Lynn, Dec. 8, 1823. JOSEPH DIXON.

* *Copperas.*

Reports of the several Committees of the Worcester Agricultural Society.

REPORT No. 1.

Committee on Neat Stock other than Working Oxen

Rejoice Newton, of Worcester, Chairman; Joseph F. Tabrook, of Royalston; Levi Bartlett, of Rutland; Daniel Tenny, of Sutton; Joshua W. Leland, of Grafton.

The Committee on Neat Stock other than Working Oxen, congratulate the Society in the County, and indeed the country generally upon the unusual exhibition of Stock which this day come under their inspection. They can safely say that the Show has never been equalled in this County, either in number or quality. It proves, in the most unquestionable manner, the influence of Agricultural Society upon the best interests of the community; it defeats the predictions of many, that the spirit of enterprize, that was manifested at the earl exhibitions of this Society, could not be kept without great individual exertions and sacrifice. Your Committee are now fully persuaded, that the good sense of the yeomanry of this County will never suffer an institution to lag or labor which is so directly calculated to promote the individual happiness as well as the prosperity of our common country.

All who have witnessed the exhibition of this day, must be sensible of the labors and difficulties which the Committee have been obliged to encounter. The examination of 171 animals has fallen within the prescribed limits of their duties—most of them entered for premiums. Among so many, where a number of several of the different classes were nearly balanced in their claims for premiums, and only shade of difference, it was, in some cases difficult for the Committee to give a preference; and were another Committee to make the same examination, they might, probably, in a few instances, vary in their decisions. But they have acted independently, as was their duty, and have awarded according to the best opinion they could form in the short time allotted them.

They found no difficulty in determining the first premium for Fat Oxen—that of Mr. Asa Pond, of Petersham, weighing 2,604 lbs. decidedly the best, and they have awarded him the premium of \$15—his size, make a flesh, all entitle him to it. To Col. Seth W. man, of Shrewsbury, they award the second premium of \$10, for his red ox, weighing 2,350 lbs. Mr. Artemas Dike, of Sutton, exhibited fine pair, one of which would have received premium on almost any other occasion, because there has hardly been any exhibition of this Society where he would have met such powerful competitors.

They award for the best Bull a premium of \$15, to Mr. Samuel Keyes, of Charlton; he is the most beautiful animal from the Holderness by now owned by Gorham Parsons, Esq. and the Committee had no hesitation in giving him a decided preference: he is eighteen months old, and weighs 1,300 lbs. The second premium of \$10 was for some time suspended between the bids of Col. Jacob W. Watson, of Princeton, and that of John W. Hubbard, Esq. of Worcester, both of the Durham short horns, and of fine animals. In consequence of the doubt which the Committee had, they have concluded to divide the premium between them. The

several other bulls, which, a few years ago, would have been viewed as objects of curiosity, particularly that of Mr. Taft, jr. of Uxbridge, of the Sutton breed, so celebrated for working oxen.

The show of Bull Calves, though not large, was not been surpassed in any former year.—Those of Maj. Brown, of Dudley, Mr. Alpheus Smith, of Leicester, Mr. Dunbar, and Mr. Bailey, of Charlton, and Simeon Draper, Esq. of Wokfield, all of the Holderness breed, are of superior size and make. The Committee awarded the first premium of \$8, to Major John Brown, his calf weighing 924 lbs. at ten months and twenty-two days old; and the second of \$4, to Mr. Alpheus Smith. These two are so equal, that a preference of either must be considered as much the result of fancy as of correct judgment.

Twenty-seven Milch Cows were exhibited, only one of them for premiums. The cow Col. Samuel Mixer, of New Braintree, was without question the best—the Committee awarded to him the first premium of \$15. Several others, and among them, those of Daniel May, Esq. of Sutton, Col. Andrew Smith, of Andover, Messrs. Thaddeus Chapin, and Asa May, of Worcester, S. Draper, Esq. of Brookfield, Mr. Roswell Conyers, of New Braintree, John Peirce, of Millbury, and Maj. John Brown, of Dudley, were nearly equal to those which constitute a good cow. The Committee have awarded the second premium of \$5 to that of Col. Andrew Smith. The cow Maj. Tenny would have received more of approbation of the Committee had he not been member of it; but under this circumstance, thought proper not to consider him a competitor. The first premium for Cows is confined to those taken from a lot of not less than five together, and the second to those taken from a lot of not less than three. The third is out regard to the number kept by the owner. The only doubt which the Committee had regarding this, was between the Cows of Mr. Henshaw and Mr. Henry Rogers, both of Leicester, either of which would have stood on the list had they not been single Cows.

The Committee award the third premium of \$3 to Mr. Rogers. Two Cows with their calves exhibited by Mr. Boylston, of Princeton, stood prominent among the whole collection. Mr. Boylston is entitled to great credit for the interest which he has taken in the success of our Fairs, and for the trouble and expense which he has so repeatedly incurred to advance the improvement of the stock of the County.

Fifty-two Heifers were examined by your Committee, many of them of great promise, for the dairy and for breeding stock. But few premiums could be given. The first premium of \$6, they have awarded to Mr. Job Hager, of New Braintree, for one of the descendants of Denton. The second, of \$5, they have awarded to Salem Town, jr. Esq. for one of the descendants of Holderness. Many others are entitled to notice—but they are so numerous that it would be difficult to distinguish. The Heifer Calves of one year old and under, the Committee award the first premium of \$4 to Asa Waters, Esq. of Millbury, his calf of Mr. Paul Goodale, jr. of Worcester, was a rival to that of Mr. Waters; but tak-

ing all points into consideration the Committee gave a preference to that of Mr. Waters.

For four years old Steers the Committee can give but one premium, of \$10, which they award to Mr. Simeon Phelps, of Sutton, for a very superior pair. Could they have given a second, as in all other classes of stock, it would have gone to Mr. Jabez Brigham, of Worcester; but as they could not, they hope his liberal feelings will be sufficiently gratified by the reflection that he has added much to the interest of the exhibition.

For three years old Steers the Committee award the first premium, of \$8 to Mr. Luther Whiting, of Sutton—but not without hesitation between him and those of Mr. Asa Cummings, jun. of Sutton, to whom the second premium, of \$5, is awarded. Those of Mr. Freegrace Marble, of Sutton, ought to be mentioned, as Steers of much promise.

For two years old Steers the Committee award the first premium of \$7, to Mr. Stephen Marsh, jr. of Sutton, and the second, of \$4, to Mr. Royal T. Marble, of the same town. Both pairs are twins. Others of a superior quality were offered.

For yearling Steers the Committee award only one premium, of \$5, to Daniel Tenny, Esq. of Sutton: his were the only ones offered; and the others of the Committee have no hesitation in pronouncing them worthy of a premium, which they award him on the ground that it does not interfere with any other competitor.

Much of the stock offered merely for exhibition attracted the particular attention of the Committee. The two rival families of Denton and Holderness present high claims for honorable distinction. Of the former, the sire has, for several years, stood the first in the show: his descendants have become numerous, and are among the first of kinds. The males and females exhibited on this occasion are too many to receive particular notice at a time when every thing must be done in haste, and nothing can be done except what is absolutely necessary.—The Committee cannot, however, pass over in silence, his beautiful connexions, Arabella and Tuberon, which have been imported, as they are told at an expense of about sixty guineas each, and which combine great beauty and promise: they were exhibited by Stephen Williams, Esq. of Northborough, to whom this Society has ever been much indebted for its prosperity, and to whose liberality, in this instance, must be attributed a good share of our gratification.

The rivals of Denton's family stand high in the celebrity of their youthful appearance and the promise which they offer to the farmer: but few have yet arrived to sufficient age to redeem the promise which their early years afford. It is believed, however, that they cannot fail of proving a great benefit to the stock of our country.

The Committee are fully satisfied, that whatever may prove to be the qualities of the different breeds of imported stock now among us, their introduction will indirectly improve all the stock of the country. The frequent examinations which they occasion make men better judges; they induce a more careful selection of breeders; and the improved manner of keeping and taking care of young stock is perceptible in every barn-yard in this County.

Many other animals, the Committee would be

glad to recommend to the attention of the Society—but their time has been so much occupied in examination, that they have none to spare for further comment. By order.

REJOICE NEWTON, *Chairman.*

The length of streets in London, now lighted with gas extends over 215 miles: the main pipes belonging to the four companies reaching to this distance; and from these a branch of smaller pipes, conveying the light to shops, private dwellings, &c. which may be calculated at a distance greater than the length of the main. The quantity of coal used for supplying gas amounts yearly to between 50 and 40,000 chaldrons.—*Christ, Oh.*

A circumstance scarcely credible has transpired before the Commissioners of government respecting Ireland, which casts great light on the state of that unhappy country, and proves that education and literature are not among the causes of its maladies;—it is that in 11 counties *there is not a bookseller's shop!*—Those who argue that education tends to excite discontent and insubordination among the poor, will find it somewhat difficult to apply their theory to the actual state of Ireland. The friends of education, on the contrary, will feel themselves encouraged to renewed zeal and exertion in diffusing this invaluable boon, from every new proof either of the evils which result from its absence, or of the blessings which, when rightly directed, it invariably confers.—*ib.*

Discovery in Chemistry.—A Prussian chemist, (a Mr. Salverte,) in making experiments to improve printer's ink, has discovered a process of producing from hempseed oil a new species of black pigment, which for brilliancy and intensity of color, far exceeds any black known heretofore, and promises to render Prussian black as distinguished a color as Prussian blue is at present. The inventor has not only applied it to improve printer's ink, but, also to other useful purposes, particularly as a superior blacking for tanned leather.

New-Haven and Northampton Canal.—The Engineers employed by the *Farmington Canal Company*, have nearly completed a minute survey of the route. The difficulties to be encountered are found on examination to be much fewer and less considerable than were anticipated, and it is believed that the expense will fall short of the calculations of the most sanguine among its friends. Some time must necessarily elapse, after the survey is completed before the calculations can be made, with the accuracy which is desired.—*Con. Herald.*

Another caution against clothing Children in cotton.—We are informed that about two weeks since a woman in Haddam, returning home met her child, a girl seven years old running towards her, naked, and almost charred. The whole form was burnt black. The child died soon afterwards. The clothes, which were of cotton, had taken fire in the absence of the mother.

[*Ibid.*]

Running Accounts.—Those in taverns are most rapid in their progress, and always come to an untimely end—the creditor loses, and the debtor generally becomes an object of distress.

From the Winchester Republican.

Address of Wm. M. Barton Esq. delivered before the Agricultural Society of Winchester, Virginia, at their late cattle Show and Fair.

[Published at the request of the Society.]

Gentlemen of the Society:

It would be regarded as a poor affectation of modesty, did I express any regret that the office of addressing you to day has devolved upon me. A subject of such interest and magnitude as that which now invites your attention—one, too, which has long employed the best wishes of patriotism, and the ablest efforts of genius—should certainly be approached with reserve and embarrassment: but on the importance of the theme, and the ardor which most of you have manifested in its behalf, I rest my claims to your kindness and indulgence. While I am conscious that I shall in vain attempt to clothe creation with new beauties, or impart to nature the charms of novelty and variety; I am sustained and encouraged by the reflection that creation is already furnished with flowers and beauties enough to beguile you, and that Nature's simple livery presents to honest and ingenuous minds more fascinations than all the tawdry ornaments with which foreign art can clothe her. On this occasion, it will be much more expedient to detail to you the short and simple annals of our infant institution, and to suggest to you some means by which we may effectually insure its future advancement and prosperity.

Three years ago a call was made upon the liberality and public spirit of our farmers, to aid in establishing an agricultural society in this section of Virginia; and although this invitation was proclaimed throughout the valley, so few were affected by the appeal, that but for the increased ardor and exertions of three or four individuals, aided by the scientific attainments and personal influence of one who now stands foremost in our ranks, our efforts would have been fruitlessly expended—the plan would have been ultimately abandoned—and the favored few, who have obtained knowledge from observation and experiment, would have been suffered to carry it secretly to their graves, leaving their less fortunate neighbors to continue and hand down to posterity the same rude and imperfect system of cultivation which they have followed and too generally received from their forefathers.

After having finally surmounted the opposition of those fond of continuing in what is termed "the good old way," and opposed to improvement solely because it wears the aspect of innovation, we succeeded in organizing this institution and establishing it on its present basis. As soon as the tocsin of success and triumph was sounded, multitudes flocked to our standard, and we now behold among the active and devoted friends of agriculture, the science, the wealth, and the respectability of the valley.

Much yet however remains to be accomplished. Although our prosperity exceeds our most sanguine expectations, and we may be proud to enumerate, among the votaries of our profession, names which are honored and revered for private virtues and for public services,—there are hundreds of our most useful and valuable citizens who stand aloof, silent and unconcerned spectators of our exertions, and who voluntarily exclude themselves from the honors as

well as the substantial benefits of this institution. To such we again extend the hand of fellowship; we invite them to participate in the laudable undertaking to enhance the blessings and comforts of rural life, and more extensively to diffuse the profits and advantages of successful agriculture. That such is the certain effect of institutions like this, must be obvious on the least reflection. Without appreciating the influence of that zeal and activity which emulation never fails to excite in behalf of any object to which it is directed, agricultural societies, considered merely as depositories of new truths and original information, are well worthy of support and encouragement.

Throughout a farming country you invariably find scattered here and there individuals, who, though sowing and reaping at the same time with their neighbors, and cultivating perhaps inferior land, seem to be peculiarly favored by nature, and reap an abundant harvest in seasons of general scarcity. These things, I am well assured, are not the freaks and caprices of chance or fortune. Every effort must have some cause adequate to its production; and the great end, both of experiment and speculation; is, from a series of effects, attentively observed and examined to deduce some rational inference as to the efficient causes. The object of agricultural associations is to excite a spirit of research and observation—to create a fountain to which the ignorant may resort for useful information—to furnish a medium through which the knowledge and experience of the few may be communicated to the many; and whether you convey through its channels the record of your success or failure, you confer the same benefit on the community; for to say to us what we ought not to do better enables us to determine what we ought to do. To point out the wrong road, is at least one step towards showing us the right.

Until within the few last years the cultivation of the soil, though ever regarded by the man of sense and candor as the key-stone to the grand arch of national wealth and prosperity, was viewed as an humble and degrading occupation. And in truth it must be acknowledged, that in the dull and monotonous routine of annual labor, and the ignoble drudging of sowing and reaping, there is little to captivate or elicit admiration. To exalt and ennoble art, you must convert it into science, and render it an object of intellectual effort. The arm of Roman industry was paralyzed, and her fields were devoted to barrenness until the inspired champion of agriculture led forth the rude and simple goddess, decked with the flowers of poetry, and clothed with the majesty of science. In former days to become a cultivator of the soil, was to renounce the labors of intellect and the charms of literature; to relish the enjoyments of a rustic life, was to abandon forever the comforts and pleasures of polished society. That these evils and privations are not necessarily incident to the employments of the field, has been of late years rendered abundantly manifest. With pride and pleasure we may now proclaim, that from no earthly source does social love and happiness flow in greater profusion than from the bounty of rural cultivation; from no soil does virtue spring with more vigor and luxuriance than from the soil on which we tread; in no atmosphere does genius soar with more buoyant wings than on

the pure and elastic air which farmers breathe in no arm is the nerve of patriotism more firm and athletic—in no bosom does its fire glow more intensely—than in that arm which is elevated with nature's own energies—and that bosom over whose sanctuary she presides.

To those who live under a free government and who are blessed with an equal administration of justice, the labors of husbandry are peculiarly adapted. Our laws look upon every department of labor and every rank in society with the same just and impartial eye. With us a monopoly of interest or of influence is countenanced or fostered. The mechanic—the farmer—the professional man—are all considered necessary appendages to the same grand and magnificent system, and as such are equally the objects of legislative favor and protection. There can be no collision of interest or foundation for envy among the several classes of men whose exertions are equally essential to the general welfare of a nation. Each class is part necessary to the perfection of the whole. Together, we constitute one vast chain of mutual dependencies: from this chain

"Whatever link you strike,
Tenth, or ten thousandth, breaks the chain alike."

Agricultural prosperity is far from waging war with the commercial or manufacturing interest. The farmer, the manufacturer, the merchant, the physician, the lawyer, are all constituent members of the great family, and each contributes some portion to the general weal. This division of labor is demanded by the constitution of man and the economy of nature.—Were we all farmers, who then would purchase the surplus produce of the earth, and without a demand, who would raise it? With only the excitement to labor of providing supply for domestic consumption, who would escape from the imbecility of sloth or the relish of idleness? Can we all be manufacturers, who then would provide the raw material, to sustain the laborer? Nor can we all be devoted to the learned professions. Neither can we all be rich. In making some poor, God has moral purposes to answer: indeed, wealth is relative term, expressing a more than ordinary amount of property, and can no more become universal than the whole earth can become mountain or a valley.

Farmers, you have abundant reason to be satisfied with your own condition, and little cause to envy the honors or profits of others. With the real and substantial comforts of life you are blessed perhaps beyond your due proportion and in the race of honor and ambition you speed is equal.

It becomes us, then, to silence those unworthy prejudices which we are too frequently disposed to cherish towards men of other vocations. Remember that, after all, the true criterion of honor is usefulness; and that he who serves his generation best, whatever his employment may be, will be most respected while living, and will leave the strongest claim to posthumous renown. While you are sinking under the proud man's contumely, let this reflection sustain you—that he who, because elevated by wealth and fortune, looks down with disdain on honest industry, however humble, is a man of weak intellect or a bad heart. Supremely ridiculous and pitiable would be that upstart nobility which in this country, where our greatest and

men rise often from poverty, and frequent from the laboring classes of society, would raise the rank from which it had just risen, to which, as the wheel of time rolls on, it is soon return. Whose blood, in this land of freedom and industry, has not flowed through the veins of a farmer or mechanic, and who is not exult in his honorable and athletic ancestry? The man who is ashamed of it is a traitor.

When I look around me, and discover many who have grown gray in the cultivation of the soil, and some, too, who are known as practical and successful tillers; I can but with diffidence commend many alterations in our system of farming. Though willing to admit that things are fond of novelty, yet I believe it is really true that the old are tooaverse to innovation; they are either too tenacious of ancient customs, or look with too much suspicion and jealousy on the efforts of the rising generation. A grand and prominent error in the agricultural system of Virginia—one which unfortunately bears the sanction of time and the authority of general adoption—is the practice of cultivating extensive farms. I am perfectly satisfied that if correct accounts of profit and loss were kept, it would be found that the proprietors of those unwieldy and unmanageable farms live less comfortably and realize infinitely less than those who concentrate the same land and attention in one fourth of the quantity of ground. You who are candid and who have regular accounts of your profits on farms of five or six hundred acres, will acknowledge that your clear gain rarely exceeds five hundred dollars per annum. Now if you have in one third fourths of such a sized farm, and the remaining fourth make annually one hundred and fifty dollars, which I am sure ought to be, is it not the best argument that can be offered in favor of such a curtailment? If you doubt the practicability of realizing so much on so small a quantity, I can only ask of you to suspend your opinions until proofs the most satisfactory can be produced of much larger gains being realized from a smaller quantity of ground. In Saratoga county, New-York, there was a Mr. Stimson, who made in the summer of 1821 two thousand bushels of merchantable corn from twenty acres of land, being an average of one hundred bushels per acre. Among the memoranda which were taken during an excursion to the north, (with the hope that this excursion could have gleaned from them some information worthy of notice) but two were preserved—the one noticing the extraordinary crop of corn raised by the Messrs. Pratt, of New-York, which is already in possession of the sector, and the other an imperfect sketch of the farm of Judge Buel, near the city of Albany.—Of the one last mentioned, I collect the facts as detailed. The farm of Mr. Buel contains 150 acres: the soil is principally silicious, and resembling the poor lands bordering our navigable rivers; the timber, a stunted pine, with a great undergrowth; the flat land, a wet cold soil; the lands of nature, barren and unproductive. For the last five years the average crop of corn on this farm has been fifteen bushels per acre; the average of wheat twenty-five bushels; of potatoes four hundred bushels; of cabbage, or Swedish turnip, five hundred bushels; of mangel wurtzel, upwards of six

hundred bushels; and of common American turnips, two hundred bushels. Mr. Buel sold the produce of forty acres of this poor land, in the summer of 1821, for 1500 dollars. Although we must acknowledge that Mr. Stimson and Mr. Buel are among the best practical and most zealous and successful farmers of New-York; yet when we are informed that the last mentioned gentleman cultivates land not superior in its natural condition to the poor pine hills of Frederick, from which he produces crops infinitely superior to those on our best lands; we are compelled to draw an inference most unfavorable to our system of farming and general management.

From some rough calculations which I have made, I suppose that on a large portion of the lands forming our eastern states, there are comfortably supported on each square mile, or six hundred and forty acres of land, from twelve to fifteen families. How frequently do we find that a single family subsists on the same quantity of land in Virginia with much difficulty.—We can ascribe this difference to nothing more rationally than to superior skill in agriculture.

Although, gentlemen of the society, I have already trespassed on your patience much longer than I intended, I cannot refrain from employing the present opportunity to recommend to you, in the strongest terms, the application of green crops as an enricher of your lands.—The cost of applying a crop of oats in this way will rarely exceed, under the most unfavorable circumstances, fifty cents per acre. It is impossible, without the fullest experiments, to say what the gain may be; but in all human probability it will exceed ten times the costs. No one can for a moment apprehend the least injury to the soil from such an application. I trust, then, that none will, for the sake of saving a trifling expenditure, remain longer in doubt on so important a subject.

Let me also recommend the substitution, in some measure, at least, of roots for corn, particularly as a food for milch cows, sheep and hogs. There is no crop which we cultivate in this country so injurious to our lands; there is none which requires a more constant and uninterrupted attention; and, in fine, there is none which returns so small a profit to the farmer, as the corn crop. By a little superior cultivation, the product in roots of one acre will go as far as the corn gathered from ten. In the vicinity of Boston resides a Mr. Ingersoll, who has devoted his attention almost exclusively to a pigery, which he has established on a farm containing in all but eighteen acres; on one third of this, which is the most he ever has in cultivation at one time, he cultivates roots of various kinds, the mangel wurtzel, however, being his favorite. From the produce of this six acres he raises and kills annually one hundred and sixty hogs, which have never averaged him less than two hundred and fifty weight each, making the enormous quantity of forty thousand pounds of pork annually. This pork is hardened with corn previous to killing, which he always obtains by the sale of his surplus manure. Then is Mr. Ingersoll realizing more by prudent management from eighteen acres of land, than is made by, with a few exceptions, any farmer in the county of Frederick.

Permit me once more, fellow-citizens, to invite and entreat you to join with us and aid in

accomplishing what we have so auspiciously commenced. Rest assured that, whatever your occupation may be, the surest guarantee to your success is the prosperity of the husbandman.—Although in your various careers of honor and usefulness, you may prefer to tread the labyrinth of state—and you to hold converse with other worlds, and to expatiate among the wonders of creation—and you to minister relief to bodily diseases—and you cleanse the corruption of the heart, and shed the light of immortality o'er the gloom of the grave—and you to hold the scales of justice, or to wrest from destruction the violated law;—and in all these diversified employments, your chief dependence is upon agricultural enterprise. Come, then, and walk into the field with me, and contemplate Nature robed in her own loveliness; abandon for a time the haunts of idleness and dissipation;—relinquish the vain and unsatisfying enjoyments of crowded life; come into the country, inhale the pure atmosphere of rural peace and quiet, and taste the genuine sweets of rural philosophy.

From the Delaware Gazette.

ON THE ALMOND.

The soft shelled almond, that fruit so remarkable for its nourishing power and pleasant taste, has, by supposition, (for by no other way can I account for it) been thought to belong to temperate and warm climates alone, and that we of a middle latitude must be exempt and dependent on them for a supply. But, if agriculturists will make the trial, they will find the fallacy of this opinion. They will discover that, like the vine of temperate Europe, their almond may be successfully cultivated. Nor does it require tender care or constant watching due to the vine to make it succeed; but, like the peach, it springs up from the stone, one of the most handsome, and by far the earliest tree in your garden. This circumstance requires that they should stand on the north side of the house, or northern slope of a hill, yet where a sufficiency of sun may reach the nut or ripen it; but not where the warm days of March and April may open its buds. Although to have success in bearing, a northern aspect must be chosen, yet they should be planted in a warm sandy loam, in a sunny place. The time in Sussex to cover them in the ground, is about the first of April, in the Upper counties, perhaps the middle would be more proper.

Some five or six years ago, being in Philadelphia, I procured six fresh nuts from a vessel from France, and when I returned home, I planted them, and in two or three weeks I perceived them looking above the ground; but I had no expectation of their surviving the winter. However, they did; and this year, being their first bearing, I collected from every tree from twenty to seventy nuts. No person can say but that the climate has expended its strength on them. Witness the cold and cutting winter of 1820, and the late frost in April, 1821, which, indeed, nipt the Spring buds, and perhaps would have destroyed the hope of fruit that year had they borne. But such frosts happen early, and like other productions of nature, the almond, of course, must sometimes fail: yet I must recommend to farmers, gardeners and others, the cultivation of the nut, which surpasses the most of those of American culture.

A FARMER OF SUSSEX.

NEW ENGLAND FARMER.

SATURDAY, DECEMBER 13, 1823.

Hydrostatic Press.—We have seen at the shop of P. Dow, No. 21 1-2, Marlboro'-street, a Hydrostatic Press, made by said Dow, which was designed for a *Printer's Standing Press*, and which, we learn, has been put up at the office of the North American Review.

This Press, by an easy process, is capable of giving a pressure of 150 tons. The principle on which it operates, is similar to that which effects what is called the *Hydrostatic Paradox*, by which a man by the power of his breath only, blowing into a bellows, through a small pipe, can raise the weight of his body. Water is forced by the pressure of a piston, in a pump, through a small ejection pipe, into a cylindrical vessel, containing a larger piston, which is elevated by a power proportioned to the difference between the square of the diameter of the piston in the forcing pump, and the square of the diameter of the piston which gives the pressure, multiplied by the power of lever obtained by the pump handle. This power can be increased to any amount which can be required, with no other difficulty than the insufficiency of the strongest materials to meet the pressure which may be thus obtained. This difficulty, however, may be obviated by safety valves; and as this power can be ascertained and applied to a fraction of a pound, it is, of course, easily so managed that the machine may give exactly the pressure which may be required.

This machine may be applied to various uses, among which may be numbered packing of goods in a bleachery, compressing cotton, hay, tobacco, linseed oil, cider from pomage, paper making, &c. &c. We consider it as one of the first inventions of the age, and believe it will supersede all other presses, where a powerful and regular pressure is a desideratum.

Premium Clover Seed Machine.—In our advertising department, in this day's paper, will be found a concise account of a Machine invented by Thomas D. Burrall, Esq. of Geneva, in the state of New-York. We have not seen the Machine, and are not personally acquainted with the inventor. But from the respectability of the characters of the gentlemen, who have recommended it, we can have no doubt of its utility. We hope that the attention of our New England agriculturists will be directed to this invention, and would recommend it to Mr. Burrall to forward one or more of his machines to the Agricultural Establishment, No. 20, Merchants' Row, Boston, preparatory to its introduction in this vicinity.

FOREIGN.

The Greeks appear to be advancing on the highway to ultimate success. Accounts from Ipsara of August 23, inform that "The same spirit of enthusiasm continues to prevail here in favor of independence and relatively to any attack which might be made on the island by the Turkish fleet, the inhabitants are perfectly easy, and have persuaded themselves that the island is impregnable. Fourteen brigs have sailed from this island to join the Greek flotilla assembled at Hydra, as had been agreed on. But since their departure, an Envoy from Hydra has arrived here, and has excited new ardor, by speaking like one inspired, of glorious prospects on the eve of being realized and asking for fresh assistance to achieve the most brilliant success at sea. In consequence six or eight vessels are fitting out with all speed to be sent to Hydra."

A later article, dated Smyrna, Sept. 5, informs that "The Hydriotes, Spriziotis and Ipsariotes have left Hydra with a fleet of 75 sail in pursuit of the Capt. Pacha."

Spain.—An article, dated at Madrid, Oct. 7, states, "Riego has been tried and condemned to death. He will be transferred one of these days to the Town Prison. Cavia was his judge, the nephew of the Bishop of Osma, one of the Regents, and the crime in the act of accusation is the having voted as a deputy of the Cortes for the deposition of the King during his translation to Cadiz, and the nomination of a Regency. It is impossible to form an idea of the horrible treatment to which this unfortunate man has been subjected. By a refinement in cruelty worthy of the serviles, the custody of his person was confided to Luthena one of the chiefs of the rebellion of the 7th of July, who took a pleasure in tormenting the prisoners in every possible manner. The populace were permitted, on the first day, to approach the dungeon in which Riego was confined, and to load him with insults."

Deadly catastrophe at Whitehaven.—A most melancholy accident happened last Monday evening, in the *Win. Pitt* (colliery) near Whitehaven, occasioned by an explosion of fire-damp, in consequence of which thirty-two persons were unfortunately killed, namely, fourteen men, 16 boys, and two girls. Seventeen horses were also killed. It is impossible to ascertain the particulars of this terrible catastrophe. That the explosion was occasioned by an accumulation of fire-damp, is almost all that is certainly known. The colliers were strictly enjoined to use the *Davy safety-lamp*; but, alas! familiarity with danger commonly engenders a contempt for it; and it now appears that some individual had disregarded the injunctions which were repeatedly issued for the general benefit. The unfortunate sufferers had nearly completed their day's work, and in less than half-an-hour would have left the pit! It is by no means unlikely that some one of the sufferers for his own convenience or indulgence, removed the safety cylinder of his lamp, or otherwise subjected it to improper treatment, and by so doing ignited the noxious vapor. It is already observed that a number of horses are killed; and it may here be added, that some of their drivers escaped in a manner almost miraculous.

Carlisle (Eng.) Patriot.

DOMESTIC.

Meeting of Congress and the President's Message.—Monday Dec. 1st both houses assembled, and the usual appointments were made in the Senate. Henry Clay was chosen Speaker of the House without opposition. Mr. Taylor, of New York, having declined being a candidate. Mr. Clay, on taking the chair, addressed the House in an eloquent and pertinent speech.

On the 2d Dec. the President's Message was communicated. It commences with some observations on the importance of the interests, which claimed attention, in consequence of the condition of the civilized world, and its bearing on us. The President then proceeds to give in detail a view of public affairs, and states that a precise knowledge of our relations with foreign powers is at this juncture pecuniary necessary.—That the Commissioners under the 5th article of the treaty of Ghent having disagreed relative to that portion of the boundary between the territories of the United States and of Great Britain the establishment of which had been submitted to them, a proposal has been made by our government, and acceded to by that of Great Britain, to endeavor to establish that boundary by amicable negotiation, and likewise the commercial intercourse between the United States and the British colonies in this hemisphere.—The negotiation with the French government for indemnity for losses sustained in the late wars, by the citizens of the United States, by unjustifiable seizures and confiscations of their property has not had the desired effect, and a minister will be appointed to proceed to France to resume the negotiation in this and other subjects.—In conformity to a proposal made by the Russian government a negotiation is authorized to arrange the rights and interests of the two nations on the north west coast of this continent.—In conformity with a resolution of the House of Representatives, instructions have been given to our Foreign ministers to propose the proscription of the African slave trade, in classing it under the denomination, and inflicting on its perpetrators the punishment of piracy.—Instructions have been given to our ministers with France, Russia and Great Britain to make proposals to their respective governments to prohibit privateering in future

wars.—The public finances are represented as being a flourishing state, and estimated that "there will be a main in the public Treasury on the first day of January next, a surplus of nearly nine millions of dollars."—A favorable account is given of the state of the army respects its organization and discipline, and of the instructions, the services of the Board of Engineers, a the Topographical Corps and the perfection of the discipline of the Military Academy.—The state of the militia is adverted to and recommended to the attention of Congress.—The Report of the Secretary of the Navy is referred to as furnishing an account of the administration of that department. The patriotic zeal and enterprise of Com. Porter are spoken of in terms of approbation. Orders have been given to all our purchases to seize and bring in American vessels engaged in the Slave Trade, but none so employed have been covered. The conduct and services of the navy highly commended, and the President observes that "it is supposed that higher grades than now exist in law would be useful."—A Report of the Postmaster General is referred to as shewing the present state that department, and its general operations for so many years past. "There is established by law eighty-four thousand six hundred miles of post roads on which mail is now transported eighty-five thousand seven hundred miles! There are five thousand two hundred forty post-offices in the Union and as many postmasters. Although the postage which has accrued within the last three years has fallen short of the expenditure two hundred and sixty-two dollars and forty-six cents it appears that collections have been made from out standing demands."—A review of the tariff is recommended for the purpose of affording additional protection to those articles which we are prepared to manufacture, or which are more immediately connected with the defence and independence of the country.—With respect to the public accounts, the President remarks that "of the money, drawn from the Treasury the 4th of March, one thousand eight hundred and sixteen, the sum remaining unaccounted for on the thirtieth of September last, is more than a million and a half of dollars less than on the thirtieth of September preceding; and during the same period a reduction of nearly a million of dollars has been made in unsettled accounts for money, advanced previously the fourth of March, one thousand eight hundred and seventeen."—The struggles and sufferings of Greece are spoken of as subjects of sympathy, and how expressed that Greece will become again an independent nation.—Some notice is taken of the efforts made by Spain and Portugal to improve the condition of the people of those countries, and it is intimated that it would best comport with our policy to take no interest in European concerns. But as regards the governments who have declared their independence, we maintained it, and whose independence we have great consideration, and on just principles acknowledged, we could not view any interference for the purpose of oppressing them, or controlling, in any other manner than as a manifestation of an unfriendly disposition towards the United States.—The Message is concluded by a summary view of the improvements in all the circumstances, which constitute the happiness of a nation, which this country has exhibited in the acquisition of territory, increase and expansion of population, the happy effects which have followed from the adoption of the constitution, in "elevating the character and in protecting the rights of the nation, as well as individuals."

Cheshire Bank Bills.—We have seen one of the counterfeit bills, since our last. The check letter is not D, as we had been previously informed. It is further evident that the true dies have not been stolen. The engraving of the counterfeit bill is by no means perfect, and its general appearance, (though imitation is remarkably good) is sufficient to detect a fraud, after once comparing the good with the bad. The following marks are infallible. In the bad bill the end of the sickle in the hand of the vignette figure rises above the roof of the house, and in the true bill it falls short. In the true bills, over the word "Five Dollars," printed orally, in the left hand die plate, the little o's are perfectly legible, in a chain—in the counterfeits they do not fall below the other word, and

to be distinguished. Other defects might be pointed out, but these are deemed sufficient.—*N. H. Int.*

week or two since a Post-manteau, containing sundries of clothing, papers, &c. belonging to the Rev. Baldwin, Episcopal Clergyman, and a trunk, belonging to the Hon. Noyes Barber, member of Congress at this state, containing about 200 dollars worth of ring, were stolen from the Mail-Stage between this and Stamford, and on Tuesday last suspiciously arrested on a couple of black fellows named Harry Jesse Sellick, living in Darien, they were apprehended, and confessed their guilt. It appears that Har- who is an old offender, took the property and gave it to the other to sell intending to divide the profits. The greater part of the articles have been recovered, the rogues are now in jail, awaiting their trial.

—*Norwalk Gazette.*

fires.—On the 27th ult. two large barns, situated in New Haven, one in the occupancy of the stage proprietors, and the other of Mr. Morse, keeper of the land stage house, and both the property of Mr. Han Peck, were destroyed by fire. All the horses in stage proprietors were saved, but four horses and a cow were burnt in the stable of Mr. Morse. The fire first appeared. The loss is said to have been considerable, but we have seen no estimate of its out. The fire is believed to have been the work of incendiary. On the same night a barn, belonging to Mr. David Mills, Innkeeper, Hartford, Conn. was burned by fire.

We learn, says a Norfolk paper of Dec. 1, that the Independence 74, now at Boston, is to be fitted out immediately, armed on flute, as the flag ship of Com. r, on the West India station. She will not be in readiness to accompany the squadron, now fitting out Washington, but will sail in a short time after, as a ship, for Matanzas, which, it is said, will heretofore rendezvous of the flag ship.

A hog 26 months old, owned and fattened by Mr. T. New-London, Conn. weighing 1250 pounds, girth 44 inches, and length 9 feet was shipped for New- on the 24th ult.

An Ox, fattened by Mr. Edward Wilson, of Troy, in bounty, was killed on the 25th inst. weighing 1401 and had 146 lbs. tallow. This Ox was kept at until the middle of June, when Mr. W. commenced feeding him with grass and potatoes. He was one pair which had been owned by Mr. Wilson seven years; and besides doing the usual work on the farm drawn upwards of 700 cords of wood to market in 10 miles.—*New Bedford Mercury.*

Premium Hats.—The premium Hats made by St. were on Thursday sold at auction for \$24, which was generously given by the maker of the hats, to the officers by fire in Maine.—*N. Y. Com. Adv.*

Another Warning.—Mr. Elijah Pillow, of Cranberry- (Norwalk) was killed last Friday, while in a of intoxication, by pitching before the wheel of a cart while he was driving.—*Norwalk Gaz.*

Crucially to Beasts.—A man was convicted and fined \$5, on the 26th ult. for beating his cattle unmercifully for profane swearing.

Accident.—A man was lately killed in Pennsylvania, by a cannon shot, while with a party, celebrating the day of Mr. Shulze. He was passing heedlessly a distance from the cannon's mouth, when it was to the point of being discharged.

Spilling out the contents of a bottle of Saratoga which had stood several years in a cellar in Carolina, there were found in the bottle well de- crystals of calcareous spar.

Death of the Russian Minister.—On the 1st inst. Baron von Bismarck, Resident Minister of Prussia, died at his place near Georgetown. On the 4th inst. Congress passed a law giving opportunity to the members to pay respect to the deceased by attending his funeral.

At Powder Mill of Messrs. Laffin, Loomis & Co. at this, was blown up on the 26th ult. and two men (Quigley) injured so as to cause their deaths.

Erratum.—In our last paper, page 147, 3d column, top line an important error occurs, in copying Dr. Fiske's Address, which our readers are requested to correct. Instead of "groping for a candle or a candle," it should have been "groping for a candle or a candle."

Complete files of the first volume of the New England Farmer, will be received in exchange for the second volume of the same paper at this office.

PREMIUM CLOVER SEED MACHINE.

THE subscriber has recently invented a new and simple mode of *hulling and cleaning CLOVER SEED*, by which the tedious, expensive, and troublesome process now in use is entirely avoided. The MACHINE for the purpose combines great lightness and simplicity, with strength and durability. Its originality, and the astonishing rapidity with which the seed is cleaned, depend chiefly on the use made of the currents of air raised on the face of a revolving cylinder armed with iron teeth. By a very simple arrangement the chaff containing Seed, in passing over the cylinder, is winnowed, and all the light chaff, leaves, dust, &c. are blown away. It then falls into the bed of the Machine, where the seed is whipped out lightly, without rubbing or grinding. When separated from the hull it falls through a screen into a fan, while the chaff is carried over the cylinder and discharged. In this way most of the uncomfortable dust of other machines is avoided, as the hull is merely broken, but not reduced to a powder; the Machine is kept free from clogging, works with a light and even motion, and requires less than one fifth part of the power necessary to other modes of hulling. No heat is raised, and not a seed is wasted or injured.

The subscriber offers RIGHTS to the above Machine for sale on liberal and easy terms, by Town, County, or State. He will also furnish Machines on reasonable notice, warranted to clean from six bushels to three tons of clean Seed in twenty-four hours, according to the size required. The hand Machines are of the size of a common fanning mill, and easily worked.—The largest size require a moderate water power.

THOMAS D. BURRALL.

Geneva, November, 1823.

RECOMMENDATIONS.

The Committee of the Agricultural Society for awarding the Premium on the best Machine for Threshing and Cleaning Clover Seed, have awarded said Premium to Thomas D. Burrall, Esq. of Geneva.

The Committee are unanimously of opinion, that Mr. Burrall's Clover Machine, with reference to the moderate expense of building, durability, the power required to work it, the quantity of Seed cleaned in a given time, and the style of performance, is decidedly superior to all other Clover Machines with which they are acquainted.

H. B. GIBSON,

NATHANIEL JACOBS,
CHARLES W. HENRY,
ANSON MUNSON,
Z. BARTON STOUT,
MARK H. SIBLEY,

Annual Fair, Canandaigua, Oct. 28, 1823.

We hereby *Certify* that we have examined Mr. Burrall's Machine for Hulling and Cleaning Clover Seed, and have seen it in operation by horse-power. Its motion is light and smooth, and it cleans with ease rising of one and a half bushels per hour. The work is perfectly well done: no Seed is injured or wasted. It is simple and durable, and we think it decidedly superior to any other Machine for the purpose with which we are acquainted.

ANTHONY D. SCHUYLER,
JOHN B. RUMNEY,
GEORGE GOUNDRY,
ANDREW MNAB.

Geneva, October, 1823.

The subscriber has pleasure in adding his testimony to the merits of the Clover Threshing and Cleaning Machine invented by Thomas D. Burrall, Esq. of Geneva. He has no hesitation in saying that he considers it preferable to any Clover Machine now in use, and that it is calculated to be an important aid in advancing the interests of the agricultural community.

NATHANIEL ALLEN.

Richmond, 29th October, 1823.

NEW ENGLAND MUSEUM.

75, COURT STREET, BOSTON.

CONTAINING much more numerous Collections and greater variety of entertainments than any other Establishment in America, continues steadily to increase, and is open for the reception of visitors.

EVERY DAY AND EVENING.

It will be constantly in the best possible condition, and every exertion made to render the visits of its patrons agreeable.

This Establishment now contains FIVE former Museums united in ONE, together with very great and numerous additions (the whole receipts being faithfully laid out to increase it.)

JUST ADDED.

The celebrated Race Horse Eclipse, A beautiful Cosmorama View of London, A large and beautiful live Rattlesnake, The Arabian Bottle, made of the stomach of a Camel—holds about a barrel—used to carry water across the desert.

The Invalid's Chair—very ingenious—invented by Professor Peck.

A very large and elegant Sword Fish, upwards of 14 feet long, with a sword 4-2 feet long.

The Museum is well lighted, and a Band of Music performs every evening. Admittance 25 cents.

PRICES OF COUNTRY PRODUCE, &c.

MIND AND BODY.

From the last number of the New Monthly Magazine.

"VELUTI IN SPECULUM."

Says Mind to body Pother day,
As on my chin I plied my razor,
Pray tell me—does that glass pourtray
Your real phiz, or cheat the gazer?

That youthful face, which bloom'd as sleek
As Hebe's, Ganymede's, Apollo's,
Has lost its roses, and your cheek
Is falling into fearful billows.

The crow's fell foot hath set its sign
Beside that eye which dimly twinkles;
And look! what means this ugly line?
Gad zooks, my friend you're getting wrinkles!

That form which ladies once could praise,
Would now inspire them with a panic;
Get Byron's belt, or Worcester's stays,
Or else you'll soon be Aldermanick.

At sight of that disantiated top,
My very heart, I must confess, aches;
Once famous as a Brutus crop,
You now are balder than Lord Essex.

Since Wayte's decease your teeth decline;
Finding no beautifier near 'em,
Time's tooth hath mumbled two of thine,
Well may they call him—"edax rerum."

Behold! your cheeks are quite bereft
Of their two laughter nursing dimples,
And pretty substitutes they've left—
(Between ourselves) a brace of pimples!

The fashions which you used to lead,
So careless are you, or so thrifty,
You must neglect when most you need,
A sad mistake when nearly fifty.

Stop, stop, cries Body—let us pause
Before you reckon more offences,
Since you yourself may be the cause
Of all these dismal consequences.

The sword you know, wears out the sheath,
By steam are brazen vessels scatter'd;
And when volcanoes rage beneath,
The surface must be torn and shatter'd.

Have not your passions, hopes and fears,
Their ligament of clay outwearing,
Done infinitely more than years,
To cause the ravage you're declaring.

If you yourself no symptoms show
Of age—no wrinkles of the spirit
If still for friends your heart can glow,
Your purse be shared with starving merit.

If yet to sordid sins unknown,
No avarice in your breast has started,
If you had not suspicious grown,
Sour, garrulous, or narrow-hearted.

You still are young, and o'er my face
(Howe'er its features may be shaded)
Shall throw the sunshine of your grace;
And keep the moral part unfaded.

Expression is the face's soul,
The head and heart's joint emanation;
Insensible to Time's control,
Free from the body's devastation.

If you're still twenty, I'm no more,
Counting by years how folks have blunder'd!
Voltaire was young at eighty-four,
And Fontenelle at near a hundred;

From the Manufacturers' and Farmers' Journal.

JONATHAN'S VISIT TO THE STEAM-BOAT.

Did you ever go down to the Steam-boat?

By jings! I'll knock under to that!

I can't hardly tell what to make on't,

It does beat creation all flat!

Why, that great copper kettle; my patience!

I'd tell what it holds, if I could.

An' it beats all our Nancy's relations,

To see how they heave in the wood!

Then them wheels all a going and jangling.

'Tis strange how they ever can sleep—

An' long iron rods, all a sprangling

Lord sakes! what a thrashing they keep!

The great wheels too, that paw up the water,

An' send up a hoghead, a stroke?

Then that big iron chimbly's a snorter!

By cat owl! how't sends out the smoke!

I swager! 'twould puzzle a fellow

To find out the head or the stern!

Why, one o' the rooms in the cellar

Is as long as the side of our barn!

MISCELLANY.

ANECDOTES.

Production of the Press.—An Irish hand-bill was printed in Dublin, of which the following is a copy. "In the press, and will speedily be published, by subscription a large cheese; price, to subscribers, two-pence a pound.

N. B. This is the first *Cheshire* cheese ever made in Ireland.

Remedy for a Leak.—An Irishman on board a pinnace, which leaked at sea, set about boring a hole through the bottom, as he observed to let out the water.

A Large Pit.—A gentleman in Ireland having built a large house, was at a loss what to do with the rubbish. His steward advised him to have a pit dug large enough to contain it. "And what?" said the gentleman, smiling, "shall I do with the earth which is dug out of the pit?" The steward with great gravity, replied, "Have the pit large enough to hold all."

DEFERRED ITEMS OF INTELLIGENCE.

Pillow Cases.—The Boston Daily Advertiser says, "We have seen a specimen of pillow cases, woven entire without seam at the sides or bottom. We understand that this mode of weaving is the invention of a young woman in New Hampshire, who weaves them with her own hands on a common loom."

Old Age.—There is now living in Sanford, Mr. Moses Tibbets, aged ninety-nine years and eight months, who attended town meetings and voted for Representatives to Congress at the last trial. He still retains the use of his limbs, is able to work and converse with freedom and sensibility.—Old age is his reward, for temperance and industry.—*Kennebunk Gazette.*

Goose Shooting.—A duel was fought lately, at the borders of the District of Columbia, between Lieuts. Tilden and Legare, of the U. S. navy, in which one of Tilden's legs was broken and the other wounded. A cunning expedient to prevent his running away!—*Greenfield Gazette.*

Great Crop.—Col. John Wilson, of Deerfield raised last year a turnip, which weighed, without the top, upward of 13 lbs. He has also raised this year, upon a little more than two three rods of ground, eighty-four bushels of Rata Baga turnips, being at the rate of something more than eleven hundred bushels by the acre.

American Calico.—We have seen a sample calico made at the new bleaching and calico printing establishment in this town, belonging to Messrs. Crocker, Richmond & Otis. The establishment is designed to be on a scale considerably extensive, and will not be in complete operation short of two or three months. It is constructed of brick, and encloses or nearly encloses, an area of several acres square; a part of one side of the building is two stories and the remainder one story high.

It has been built, and is to be carried on, we understand, under the superintendence of J. Thorp, lately from a manufactory of this kind in England. There are but three or four establishments for the manufacture of this article in the U. States; one at Philadelphia; one at Chelsea, and another at Charlestown, in this State. The two last we believe are not yet completed.—*Taunton Reporter.*

Fire.—At Hebron, on Tuesday last, three large and valuable barns, filled with the produce of the season, were destroyed by fire. They were owned by Mr. Joseph T. Burnham, and stood adjoining each other. The accident was occasioned by leaving a candle burning in one of the barns, where Mr. Burnham's sons had been husking corn, very early in the morning.—*Hartford Times.*

Astronomical Notice.—There is at present clear evenings, a most favorable opportunity observing those two interesting planets of solar system, Jupiter and Saturn. The latter sets at between 7 and 8 P. M. and his situation a little to the south of the small cluster of stars in the neck of Taurus, which are called Pleiades. Jupiter rises between 10 and P. M. and may be seen near Gemini, at a distance to the south of the stars Castor and Pollux. This latter planet is easily distinguished by his superior brightness and magnitude and a good 12 inch telescope will shew distinctly that wonderful phenomenon of the rings of Saturn, also the four moons and belts of Jovian.

Shows.—The Town Council of Harrisburg, Penn. have passed an ordinance expressly bidding and prohibiting, "within the borough all kinds of puppet shows, jugglery, and slight hand performances."

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

No. 21.

FROM THE AMERICAN FARMER.

The brief, but comprehensive remarks of Mr. B. upon the habits and productiveness of the several kinds of grass mentioned in the table, are more acceptable as coming from one, who, with extensive reading, unites diligent and judicious personal investigation by actual experiment in his own farm, and with his own hands. It would have been more satisfactory to have given the whole communication in one paper, but we are obliged often to forego our own judgment, for the sake of consulting the better taste of our readers, many of whom, as we have lately been advised, have an aversion to what they call *long articles*; rather preferring, we sometimes fear, variety, to solidity of information—as the mass in audience prefer laughing at the antics of MATTHEWS in the “Polly Packet” rather than view, with breath-suspending admiration, the great wrakings of the human soul, as exhibited by KEAN in the most pathetic passages of Othello.—Our own taste is the other way, but *de gustibus non est disputandum*, and moreover the Farmer belongs to its patrons and not to its Editor.—The observations of Mr. B. on *Long-rooted clover*, *Sain Foin*, *Hoathy*, *Florin*, *Upright bent grass*, *American Cock's foot*, *Flat stalked meadow grass*, *Reed meadow grass*, *Smooth stalked meadow grass*, *Flouting*, *Ice grass*, *Cultivated grasses*, *Meadow grasses*, and *Pasture grasses*, will appear in our next.—*Edit. Am. Far.*]

hibiting in one view, the comparative value of some of the best Grasses cultivated in the United States, and in Great Britain, their products, nutritive matter, time of flowering and seeding, &c.

NOTE.—Those marked with an *, are indigenous, or native plants of the United States.

TO THE EDITOR OF THE AMERICAN FARMER.

SKINNER.—I have found in our publications agriculture, very little information on the improvement of our meadow and pasture grounds.

Indeed, the names of our native grasses are scarcely enumerated much less are their habits described, or their relative merits, for hay and pasture, pointed out in any American work which has fallen under my notice. A considerable portion of our lands are unsuitable for the system of convertible husbandry, that is, an alternation of grain and grass crops. Of this description are our stiff clays, marshes and swamps and all those lands in which tillage is rendered

difficult, by reason of hardpan, stones or habitual wetness. These should be improved as permanent meadows and pastures; and it is of the first importance to the farmer to know the grasses which will render them most conducive to profit: for that our grass lands are as susceptible of improvement as our tillage grounds, by a judicious selection of seeds, and suitable management, must be apparent to every reflecting mind. The improvement and productiveness of our cattle and sheep husbandry, which at this time deservedly engages much of the public attention, must depend materially on this branch of farming.

With a view to inform myself on this subject, I have been examining several British publications, which abound with information to the *English Farmer*, and are not without their interest to the *American cultivator*. But this information is so diffuse, and so much of it inapplicable to our husbandry, that I have been induced for my own gratification and benefit, to collect some of the most material facts in a condensed form, which, with some remarks of my own, I herewith communicate for publication, should you deem them worthy of a place in the *American Farmer*. I do it in the hope that its publication may induce experiments at home, and elicit useful information from gentlemen of science and practical knowledge on the subject of grasses, particularly those which are indigenous to our country. The table is compiled from the appendix to Davy's agricultural chemistry. It is to be regretted that it embraces only nine species of American grasses. It, however, contains several approved foreign kinds, most of which have been more or less introduced among us already.

To those who do not possess Davy's work, it may not be amiss to say, that the results stated in the table may be implicitly relied on for correctness. The experiments were carefully made by George Sinclair, under the direction, and at the expense of the Duke of Bedford, at Woburn, in England.

Sweet scented Vernal Grass.—This is a grass of diminutive growth, and it will be seen by the table, is not worth cultivating for hay. It is, nevertheless, considered valuable in pasture, on account of its affording very early feed, and growing quick after being cropped. We are advised by Muhlenburgh that it delights in moist soils; by the Bath papers that it does well in clayey loams, and by Dickson, that it grows in almost any soil, including bogs and sands. G. Sinclair, says it is eaten by oxen, horses and sheep, though not so freely as some other grasses are.

Meadow Fox-tail, possesses all the advantages of early growth with the preceding, and is much more abundant in product and nutriment. It generally constitutes one of five or six kinds which are sown together by the English farmers for pasture; and affords, withal, a tolerable crop of hay. It does best in moist soils, whether loams, clays, or reclaimed bogs. Sheep and horses have a better relish for it, says G. Sinclair, than oxen.

Rough Cock's foot.—Dr. Muhlenburgh and T. Cooper, concur in the opinion that this is the *orchard grass*, of the United States; though some that I have raised as *orchard grass*, does not seem to correspond with the figure of the *Dactylis*

Glomerata, in the 2d vol. of Dickson's *Farmer's Companion*. In England cock's foot is taking the place of rye grass, with clovers. Arthur Young speaks in high commendation of it; though all writers concur in the opinion, that it should be frequently and closely cropped, either with the scythe or cattle, to reap the full benefit of its great merits. I should prefer it to almost every other grass; and cows are very fond of it. Cooper rates it above timothy, and says it is gradually taking the place of the latter, among the best farmers about Philadelphia. This is probably owing to the fact, that it is earlier than timothy, and of course more suitable to cut with clover for hay. Its growth is early, and rapid after it has been cropped. It does well on loams and sands, and grows well in shade.

If further facts are wanting in favor of this grass, for pasture, the reader will find it in the *American Farmer* of the 14th November, in an article signed Curwen, which, if I mistake not, means Col. Powell, of the neighborhood of Philadelphia, a gentleman who combines as much science with judicious practice, especially in cattle and grass husbandry, as any person in the union. He says, "I have tried orchard grass for ten years. It produces more pasture than any artificial grass I have seen in America." Sown two bushels of seed on an acre.

Tall Out grass.—Both Arator, (Mr. Taylor,) and Dr. Muhlenburgh have placed this at the head of their lists of grasses, which they have recommended to the attention of the *American Farmer*. The latter says it is of all others the earliest and best grass for green fodder and hay. The Doctor was probably not advised of its deficiency in nutritive matter, as indicated in the foregoing table. It possesses the advantage of early, quick and late growth, for which the cock's foot is esteemed, tillers well, and is admirably calculated for a pasture grass. I measured some on the 20th June, when in blossom (when it should be cut for hay) and found it four and a half feet long. The latter math, it will be perceived is nearly equal in weight, and superior in nutritious matter, to the seed crop. Sinclair says it thrives best on a strong tenacious clay; and Muhlenburgh prefers for it a clover soil. Dickson speaks well of it; says it makes good hay, but is most beneficial when retained in a close state of feeding. I have sown it in autumn and spring, with clover, on a sandy loam, with good effect.

Tall Fescue, although a native grass, has not fallen under my personal observation. It stands highest, says Davy, according to the experiments of the Duke of Bedford, of any grass, properly so called, as to the quantity of nutritive matter afforded by the whole crop, when cut at the time of flowering; and meadow cat's tail (timothy) grass affords most food when cut at the time the seed is ripe. It grows naturally in wet grounds, in bog meadows, and on the sides of ditches, often to the height of four or five feet. Our ignorance of agricultural botany, and of the intrinsic value of this grass, can alone have prevented its being more generally known and cultivated. It must be very valuable for wet grounds, as from its rapid growth it is calculated to smother or keep down the coarser kinds which naturally abound in those situations.

Rye grass, is extensively cultivated in Scot-

land, and the north of England, and when cock's foot has not superseded it, is generally mixed with clover seeds. It is rather declining in the public estimation. It does well in pasture, and as it contains much nutriment, is considered valuable for cows and sheep. Dickson says it does best in rich moist meadows. Young does not speak well of it.

Red clover.—There are many species of the *trifolium*, and several varieties of red clover. Whether the kind we generally cultivate, the *pratense*, or not, I am unable to determine. The character of red clover, as an ameliorating and fertilizing crop, is too generally known to require illustration. It cannot be depended upon for permanent grass lands; though it yields to no grass in value for alternating with grain in convertible husbandry. It formerly was an indispensable in a course of crops in Norfolk England, (which has been considered pre-eminent for good tillage) as turnips; and the maxim then was, and still is, "no turnips no crops." But it appears from Young's survey of the county, that it cannot now be depended on of tenor than once in from eight to twelve years. Trefolium, white clover, cock's foot, rye grass, &c. are therefore alternated with red clover in the grass years. There is reason to believe that neither red clover, nor other grasses, will be repeating for a course of years upon the generality of soils. They exhaust the ground of the peculiar nutriment required for their support. In Great Britain, white clover, trefolium rye grass or cock's foot are generally sown with red clover seeds. From twenty to thirty pounds of seeds are sown to the acre. In the northern states, timothy is generally sown with clover; though it is evident from the table that the mixture is an improper one for hay; for the clover is fit for the scythe ten or fifteen days before the timothy has attained to maturity. If sown alone, from eight to sixteen pounds of clover seed should be put on an acre: more on old land, than on new.

White, or Dutch clover, (*Trifolium repens*.) is considered, in England, of importance to husbandry, if we are to judge from the great quantity of its seed which is there sown annually. With us, many districts, produce it spontaneously; but it is too seldom sown. It shrinks greatly in drying, and does not contain as much nutritive matter, as red clover; yet its value, as a pasture grass, is universally admitted. Its increase is very much facilitated by a top dressing of gypsum, lime or ashes.

Lucern, although affording much more green food, contains less nutriment in a single crop, than red clover. It must, however, be borne in mind, that it grows much quicker than clover, and will bear cutting twice as often. In the soiling system, an acre of lucern will keep four cattle or horses from the 15th May to the first, of October. I cut a piece last summer about the 15th May, and again about the 20th June, to feed green, and then ploughed the ground, and cropped it with ruta baga, which yielded sixteen tons the acre of roots, as fine as I ever saw. Mr. Fowell (see Young's Norfolk, p. 345, derived a) clear profit of £13 17s 4d. per acre from his lucern, fed green to working horses. This is almost equal to \$60 the acre. An idea has prevailed, that, it will not thrive in this latitude, (42—3); but the experiments of the late Chancellor Livingston, and

Le Ray de Chaumont, prove otherwise. I sowed seed in 1821, at the rate of 6lbs. the acre, of such barley. It has stood the winters well, much better than clover; and has been in a state of progressive improvement. Drought has not affected it. The plants are very tender the first year; and require either a very shallow tith, or to be kept free from weeds and grass with a hoe the first year. It should be in a deep loam, as it sends down tap roots three or six feet; and it is equally necessary that the ground should not be wet. It may be sown either in drills or broad cast, with or without grain. Fifteen pounds of seed are required for the acre if drilled, and 20 is not too much if sown broad cast. To the proprietor of a dairy, an acre or two of lucern would be valuable, to be fed to his cows, in addition to ordinary pasture.

(To be concluded.)

From the New York Advocate.

PICKLE FOR BEEF AND PORK.

The following recipe for making pickle for beef and pork, is strongly recommended to the adoption of those who pickle beef and pork for family use. Persons in the trade, who will adopt it, will find it a ready sale for their beef and pork. It has been used by many families in this city, and always improved. I do not hesitate to assert that there is no pickle in use to be compared with it. It is familiarly known by the name of the "Knickerbocker Pickle." Could this recipe be generally adopted, our pickled beef and pork would have a preference in the foreign markets.

RECIPE.

12 gallons water, 9 lbs. salt, coarse and mixed 3 lbs. brown sugar, 3 ounces salt pepper, 1 ounce pearl ash, 1 gallon molasses to every 12 gallons water.

In making a larger or smaller quantity of pickle the above proportions are to be observed. Boil and skim these ingredients well, and when cool, put it over the beef or pork.

AN OLD HOUSEKEEPER.

From the American Farmer.

PRESERVATION OF FOOD.

On sea voyage, though it generally produces a good appetite, does not as often furnish the means of gratifying it; and a ship, either for comfort or luxury, is not usually the place where those who attach value to such matters, can be accommodated.

All pleasures are comparative, and the accommodations, personal and gastronomic, of those who from whatever cause are at this day induced to venture on board ship, are so much increased beyond any thing known to the older times, that, in that sense, they may be truly said to be both comfortable and luxurious.

Among the wants which are most sensibly felt at sea, and which modern refinement and ingenuity have found the means of remedying, is that of fresh provisions. In this respect, Messrs. Messett and Daggett, of this city, have accomplished so much that they can put up fish, poultry, game, nay custards, so as to preserve them in any climate, and almost for any time, without any perceptible alteration in their original taste or quality. This is chiefly effected, we believe, by having them enclosed in tin cases, hermetically

sealed. We are pleased to learn that the use of these provisions is becoming general, and have much satisfaction in presenting to the public the subjoined testimonial of Commodore Porter as to their excellence:

Copy of a letter from Com. Porter in answer to Messrs. Daggett & Kensett of N. York, respecting his opinion of their preserved fresh provisions. Washington Nov. 13th, 1823.

"Gentlemen—Your letter of the 30th ult. should have been answered, at an earlier period but for unavoidable absence and a great press of business.

"I have given to your preserved meats a fair trial, particularly the beef and poultry, both for the Hospital department and as rations, as well as at my own table—and I have taken every occasion to recommend them not only to the officers under my command, but to others going to sea. I have taken some pains to bring them into general use in the Navy, and you may calculate on a favorable disposition on my part toward your establishment so long as, by your care and attention in putting up the provisions, you may have a title to it.

"Some of the provisions, which I took from New York last winter, are now on hand, and as good as the day they were received.

Very Respectfully,

Your obedient servant,

D. PORTER.

MESSRS. DAGGETT AND KENSETT,
616, Water street, New York."

Parsnips—Contain a very considerable portion of sugar. In Thuringia, the country people evaporate the juice until it has the consistency of thick syrup, when they eat it on bread instead of honey, and use it in many cases as a substitute for sugar.—Marmalade made with parsnips, and a small quantity of sugar, is thought to excite appetite, and to be a very proper food for convalescents. Wine made from these roots approaches nearer to the Malmsey of Maderia and the Canaries, than other wine; it is made with little expense or trouble, and only requires to be kept a few years to make it as agreeable to the palate as it is wholesome to the body; yet fashion induces us to give pounds for foreign wines, when we can obtain excellent wines of our own country for as many shillings. In the northern parts of Ireland the poor people obtain a sort of beer from parsnips, by mashing and boiling the roots with hops and then fermenting the liquor.

Steam Boat improvement.—It is mentioned in a late Montreal paper, that a new steam boat has been built there for the purpose of towing vessels on the St. Lawrence which on her first trip went 45 miles in four hours and 20 minutes; sailing against the most rapid part of the current with ease, and where no vessel had ever been able to pass, without the assistance of a strong wind. The machinery of the car of the *Car of Commerce*, belonging to Montreal, and of only fifty horse power, is said to have cost upwards of \$5000. That of the new vessel (named the *Hercules*), of 100 horse power, cost the proprietors \$4500.—This last vessel was built under the superintendence of Mr. A. Young, and appears to have excited a great

portion of interest among the mercantile community of Montreal.

Oysters.—When too many oysters have been incautiously eaten, and are felt lying cold, and heavy on the stomach, we have an infallible and immediate remedy in hot milk, of which half a pint may be drunk, and it will quickly dissolve the oysters into a bland creamy jelly.—Weak and consumptive persons should always take this after their meal of oysters.—*Family Oracle of Health.*

Means of Preserving Eggs.—Make lime water as strong as quick lime will make it, and keep the eggs you wish to preserve constantly covered with the said lime water. The vessel containing the eggs and the liquor in which they are preserved should be kept covered so as to exclude the air; otherwise the lime water will gradually lose its strength, together with its power of preserving eggs.

Good news for the Agriculturists of New-York.—

Gen. S. Van Rensselaer, always studious of using his ample means to promote improvements in Agriculture, has placed \$1000 in Liverpool, to be invested in neat cattle, of improved breeds. To those who reflect how much time and money have been devoted in this country to attain the highest degree of perfection in all the qualities for which domestic animals are valued, it must be obvious that great benefit will now result from transplanting to our soil the matured fruit, produced by the skill and labor and close attention of more than half a century.

[*American Farmer.*]

A machine has been submitted to the French Government, for throwing water into the enemy's ship during action so as to prevent the vessel being worked. This machine, which can be worked by ten men, will throw, at every stroke, upwards of two tons of water a distance of more than forty yards, if required, and thereby prevent the possibility of working the opposing ship.

Dr. Walker, Professor of Natural History in the College of Edinburgh, remarked of the *Lauristinus* and *Furze*, that it was easy to see they were not natives of Scotland, "for no sensible Scot's plant would ever think of flowering at Christmas."

Lime wet, and lowered to the bottom of a well, or as far as the water will permit, to slack, is found to free it promptly and entirely from the air which is so frequently fatal to persons who descend. A candle should be let down to ascertain that the air is depurated.

Turnip Crop.—On half an acre of ground was raised this season, by Dr. Matthias Spalding, of this town, 290 bushels of good English Turnips. This crop obtained the premium at the late cattle show.—*Amherst Cabinet.*

Keep to the Right.—The following singular notice has been placarded on the walls in Liverpool Eogland:—

"Respectable People are requested to keep to the right hand side of the footpath and Blackguards the left."

From the Acadian Recorder.

Halifax, Oct. 8, 1823.

JOHN YOUNG, Esq.

SIR—If you think the following hasty statement on one of the most important branches of our Industry and Trade worthy the notice of the public, you are at liberty to have it inserted in one of the newspapers.

I have heard it asserted by persons here, who have cured provisions for home consumption that pork or beef after being frozen was not fit for a foreign voyage, either dried or pickled; but this is without foundation; as the subjoined statement will shew the quantity exported by Higgins & Brown to the West Indies, (chiefly to Kingston, Jamaica) or sold to vessels in the W. I. trade. All these provisions, although purchased by them in a frozen state, have given satisfaction; and in fact they never had a complaint of such as were put up by themselves.

Shipped in 1821,—12 barrels Pork; 16 barrels Beef; 1 cask Jowls and Shoulders dried, 554 lbs.

Shipped in 1822,—20 barrels Pork; 21 barrels Beef; 50 Hams, 650 lbs. 1 cask Jowls and Shoulders, 690 lbs.

Shipped in 1823, before the 9th of last April, 13 barrels and 8 half barrels Beef; 1 cask Hams, 343 lbs; 1 cask Jowls and Shoulders 475 lbs.

State and value of the provisions cured in 1823, either on hand or shipped as above, before the 9th of last April,

120 bbls. Pork, at 20s.	£120 0 0
50 sides Bacon, supposed value	80 0 0
50 Hams, do. do.	175 0 0
1200 lbs. rendered Lard at 3d.	40 0 0
43 bbls. Beef, at 60s.	144 0 0
	£359 0 0

And in addition we received from our customers, to the above date, quantities of smoked meat, butter, lard, about 6 tons oatmeal, value £105, and homespun cloth being all the growth or manufacture of the province. It must be gratifying to you as well as to every true friend to the agriculture of this country, to learn that the provisions shipped have averaged a profit; which is the best reward we can have, both operating as a stimulus to our future exertions, and enabling us to give a fair remunerative price to the farmer. The rate of pork last winter was thought too low, but this certainly is not the case, as every thing has of late experienced a depreciation. It is the interest of the farmer to sell as low as possible, as he will thus increase the demand and be repaid for his trouble by the additional quantity raised. This argument will appear the more convincing when he considers that pork is fed on the refuse of the farm, which cannot in any other way be so advantageously brought to market.—Should you deem it of service to the agriculture of the country, I have not the least objection to give the method we pursue in curing provisions generally, and our hams have sold for higher prices than any cured in the place. We have been told by several officers of the army and navy that they are equal to those imported from England; which I have no doubt is the case, with the exception of those that might have been fed on beech nuts. If our

farmers would take a little more pains with those hogs that they allow to roam in the woods during the fall, it would be much to their own advantage. I have often recommended to them to put such in their pens for at least four months before they were killed for market;—as without this precaution they are fit neither for hams nor bacon; and it is an injury to barrelled provision to have too great a proportion of this pork, which must be considered inferior for any purpose. I do not say, by putting pigs up for the short time above stated, that it would make them as good as if they were fed on grain; but I say that it would improve them very much, and they would bring a better price. I have resided in one of the principal towns in Ireland a part of my life, from which there is an immense quantity of provisions exported; which has been a principal source of raising it to its present opulence; and there can be little doubt if this business is attended to properly in this town, it will be a principal source of its future wealth. Since I have come here, that is about seven years ago, the pork and beef have been gradually improving in quality, and increasing in quantity, but particularly within the last three or four years.

I remain, sir, your most obt. servt.

WILLIAM B. HIGGINS.

REMARKS.

This letter offers a frank and ample and, as far as we are able to judge, a satisfactory exposition of the nature, extent and results of the trade in salt provisions, which has been carried on by the Concern in town, of which the writer is partner. It is frank, because mercantile men in general affect to cast a mystery over their transactions, and are little disposed to let out any disclosure which may be presumed even distantly to touch their interests: it is ample, because it sets forth the results of his experience for the whole three years, during which the curing of beef and pork has engaged his attention;—and it is satisfactory, because it lets us into the knowledge of the very points, on which we were most solicitous to gain information—that *frozen* beef and pork can be cured without any detriment to their quality or power of preservation on a foreign voyage, and that this new trade can be conducted in Halifax, so as to yield a profit on the capital embarked in it.

It is, we believe, in the recollection of the public, that the Provincial Society, for the last two years, had strenuously recommended to the legislature to offer certain premiums, in order to stir up individuals towards the commencement of this trade; because they considered it essential to the success of our agriculture, to prevent the great and ominous depression which regularly occurs about this season of the year.—Tolerably fair beef selling at 1 1-2d. per pound was no very delightful spectacle to such as took an interest in our rural affairs, and at the time of writing this, a repetition of the same ruinous sales is occurring at auction. This letter then comes in most opportunely to stay the progress of this prodigious evil, which operates alike against the grower and consumer. That the poorer class of farmers are injured by such low prices recurring annually at the close of the grazing season is quite obvious; because they are

in no condition to keep up their stock, until the gradual demand of winter shall take off their hands at a profit, and the necessity of their circumstances thus imposes on them a heavy and vexatious sacrifice. But even to the consumer it is not advantageous to have prices too seriously disturbed—remarkably low at one time and proportionally high at another.—Such great variation in the commercial balance occasions waste and extravagance at the descending and the exercise of a penurious parsimony at the ascending scale—a state of things found, from long and uniform experience, to be accompanied with any thing but benefit to the middling and inferior orders, the chief and great consumers in every community.

There are only two ways in which a remedy can be brought to this mischief. The first is in the hand of the farmer, and sooner or later he must come to employ it in his own behalf. He must extend the cultivation of his green crop—turnips and potatoes—with the intent of enabling him to keep back his cattle at the beginning of winter, and to sell them off according to the nature and increase of the demand. In this case, the supply would never be over abundant and the market would be maintained at a remunerative level. The other remedy lies in the salt provision trade.—Were a few of our merchants to engage in it heartily, and to buy to the purpose of export, the redundancy of beef in November, December and January, would be carried off; and thus open a new, and of all appearance, a profitable branch of trade.—For some years past the main purchasers have always been the army contractors who have had it in their power to regulate, in a great measure, the price; and this want of competition has been felt as a grievance, and been represented by some as causing the great depression about which we have heard such loud and reiterated murmurs.

In estimating the value of different agricultural produce, there seems to be a standard of universal application, and which was illustrated in the last agricultural report delivered here before the society, at the meeting of the legislature. This standard consists in a certain given ratio between the price of flour, butcher meat and butter—so that whatever be the price of the first, the other two should advance in a geometrical series.—If flour be at 2d. a lb. beef should be at 4d. and butter at 8d.—and so invariable are these proportions in all countries where trade is permitted to act freely, that they are maintained in Britain, in the different European kingdoms, and as might have been expected also, in the American States. In the New England Farmer—a recent paper established at Boston, the editor, soon after the publication of the last agricultural report here, adverted to the rule laid down in it, and found that it tallied exactly with the existing prices in those States of the Union to which he at that time extended his examination. The rule therefore may be assumed as absolute, and of universal applicability; and it becomes a curious question in what manner, and from what cause, the proportion in butcher-meat only, should be disturbed here every fall—for butter never sinks below the proper standard: flour at 32s. 8d. per barrel gives the lb. at 2d, and at 40s. 10d. at 2½d.—and as these are fair quotations of the different qualities in the market, the medium between

or 2½ per lb. may be assumed as the average price at present.—According to this, which we have denominated the first term in the butcher meat should be 4½ d. and butter 9d. flour and the butter are relatively to each in their just ratio, while the middle term forms, and has always formed, every fall, exception. There is nothing clearer, I think, in the whole circle of practical arithmetic, than that beef at 1½ d. per lb. entails a dead loss in the produce; and that in order to recommend moderately, his labor and outlay, he requires double the price for it, that he asks for flour; or in other words, that a bushel of flour can be raised at half the expense of a pound of beef.—Whence it appears, that the cattle in Nova Scotia are sold at a price much lower than the rule above would seem to justify? The solution of this problem is quite simple, and calls for no painful search. Flour and butter are articles, which can easily be retained till the demand takes them off in the season of consumption; whereas cattle with farmers, who labor under a scarcity of crops and almost totally neglect turpits, are kept, after the grass is over, in a fit for the butcher, far less improved in their condition, and on this account they must be hurled to market, though at a great and inevitable loss—and with the certainty that beef will be spring to 6d.—a price as much above the rule as is below the proper level. This is our agriculture while it lasts, holds out a tempting occasion for commercial speculation, and cattle should now be briskly bought up by several of our merchants; and a moderate capital thus employed would reap a market of that glut with which it has inundated every fall to the great and security of the farming interest. At Boston a immense quantity of beef and pork is annually sold during the winter, and in this way, are there kept from the extraordinary seasons which we have witnessed. The following published will, I trust, awaken a spirit of enterprise and tempt others to engage in it vigorously in this line.

JOHN YOUNG, Sec'y.

Worcester, Nov. 14.

of the several Committees of the Worcester Agricultural Society.

REPORT No. 11.

Committee on Working Oxen.

John Hubbard, of Worcester, Chairman; William Northborough; Abel Warren, of do.; Wilster, of Sturbridge; Stephen Hastings, of do.

The committee on Working Oxen respectfully congratulate their fellow-citizens of the County of Worcester, on the additional and honorable proof this day exhibited of the superiority of the County in this important part of an agricultural exhibition.

The committee do not inconsiderately deem it to which their attention has been directed in a part of the world where the title indeed, but must be compelled to show its abundance;—where we enjoy the fruits of nature, as the fruits of victory, a voluntary gift, our Laboring Oxen con-

stitute the sinews of our Agricultural strength. Without them, our implements of husbandry would be comparatively inefficient, and the labor of the husbandman endless and intolerable. The horse, though a noble and useful animal, would be, to us, a poor substitute for the ox—in disencumbering our soil of ponderous rocks and deep and spreading roots; in the cumbrous draft over a broken and rugged surface, and in working the plough, which must be impelled with vigorous but steady force, slowly and through continual obstructions. The Ox which patiently bows his neck to the yoke, and cheerfully shares and alleviates the primeval curse, being thus especially important to us, it was to be expected that an enterprising and intelligent yeomanry would successfully exert themselves to improve the race in their possession. This day has shewn such an expectation well grounded. It may hereafter be reasonably doubted whether any section of this country or any other country can shew better Working Oxen, as patient, docile, hardy and efficient laborers, than the County of Worcester. However, the distinguished breeders of other countries may have surpassed us in improving cattle for the stall and for the dairy, yet for the yoke, your Committee confidently believe that we need no foreign blood: it would rather adulterate than improve. We would not be understood to believe or assert, that our oxen have arrived to a degree of perfection beyond the capability of improvement—but only that there exists no better breed to improve upon. Comparing the present with the preceding Shows, under the patronage of the Society, and reflecting how obviously each has exceeded its immediate predecessor, we have not only a striking evidence of the beneficial influence of the Society on the agriculture of the County, but are also encouraged to hope that the time will arrive, when the common and ordinary animals of the County will equal the best exhibited for premium to day. Knowing the usual competition in Working Oxen at our Shows, and the unusual number of entries this year, your committee anticipated much difficulty in awarding the premiums at their disposal; and they have been in no degree disappointed. They must despair of having come to a result satisfactory to the competitors, or even to all intelligent and impartial spectators, for they have but barely satisfied themselves. They have, however, judged impartially, and they hope correctly, in awarding—

The 1st Premium of \$15 to Isaac Hathaway, of Sutton. 2d do. of \$12 to Fregance Marble, of do. 3d do. of \$10 to John Sherman, of do. 4th do. of \$5 to Seth Wyman, of Shrewsbury.

Besides other obvious considerations, a regard to the age of the cattle tried, contributed to direct the judgment of the Committee. Mr. Hathaway's Mr. Marble's, and Mr. Sherman's were all of them four years old only. There were others among the rivals much heavier and somewhat stronger, Mr. Brigham's, Messrs. Ward & Rice's, and Mr Fessenden's, all from Worcester, were very fine and rich looking

* Col. Wyman having last year obtained the 2d premium for Working Oxen with the same cattle, according to the Rules of the Society cannot this year receive a premium of an inferior grade—the 4th Premium has therefore been awarded to Stephen Marsh, jr. of Sutton.

cattle; but their age and hard service had carried them past the combined vigor and activity of some of the younger competitors. Their docility also was less perfect, and they manifestly possessed less of that careful education which the farmers of Sutton are so justly noted for bestowing on their Working Oxen. The Committee had great difficulty in deciding between the Oxen of Mr. Wyman, to whom they assigned the fourth premium, and those of Mr. Marsh. It was pretty obvious however that Mr. Wyman's were better mated, and a little handier than Mr. Marsh's.

The Committee were highly gratified in being called on to view a fine display of Working Oxen consisting of nearly sixty yokes, from the enterprising town of Shrewsbury. It served to maintain and justify the deservedly high agricultural character of that town. None but an excellent farming town can have it in its power to produce such a number of superior Oxen. A farming district may be judged of by its Working Oxen as safely as by its Barns or its Cornfields.

The Committee are very happy to have it in their power, by a vote of the Society, to award to the proprietors of this team the trifling sum of 10 dollars, merely as an expression of our favorable opinion, and of the gratitude of the Society for this interesting addition to our Show.

For the Committee,

JOHN W. HUBBARD, Chairman.

Support your Mechanics.—A practice is very prevalent, in many towns of neglecting too much the mechanics of the place. Next to the farmers they are the most useful class of citizens, and yet a disposition is often felt to avoid employing them, if possible, and to withhold from them such encouragement as would enable them to be as useful as they might be, and as they ought to be. If a coat or other garment is to be made: if a pair of boots or shoes, or a saddle, bridle, or other article is to be procured, which the mechanic in the place ought to furnish, it is no unusual thing to employ a mechanic at a distance, to perform the work; or to procure the article in some way which may be nominally less expensive, but which, in reality, considering the quality of the article is considerably more so than it would be if a mechanic of the place had been called upon to manufacture it.

This practice is productive of various evils. It sends from a place the money which should be kept in circulation at home; it introduces a silly dependence upon the fashions of other places, or leads to the use of inferior articles, and a corresponding increase of expense; and by withholding such encouragements to mechanics of different kinds, and of proper qualifications, as they ought to receive, there is not a sufficient number induced to settle in a place to do its necessary mending, and consequently articles are frequently thrown away as useless, where a very small sum expended upon them would render them as serviceable as those that are new.

Great price of Tobacco.—A single hogshead of Tobacco, from the plantation of Mr. Johnson, of Frederick county, Md. was sold in Georgetown on Thursday last, at the enormous price of \$50 per hundred weight! Five or six hogsheads of a quality somewhat inferior sold at an average of about \$30 per cwt.

In England, in Oct. a young woman apparently died, after a long decline. She was laid out, and on the 14th day was removed to a coffin for interment, when signs of life were discovered, and in a few hours she was able to converse.

Something similar occurred in Boston some years since, in the case of a Mr. Cutter.—*Pulla.*

Dartmouth College.—From the catalogue of this institution just printed, the following appears as the number of students, viz. Medical, 73; Senior Sophisters, 28; Juniors, 33; Sophomores, 41; Freshmen, 39;—total, 211. The whole expense at this Seminary, including board, tuition, room rent, &c. is \$98 65 per year.

NEW ENGLAND FARMER.

SATURDAY, DECEMBER 30, 1832.

WOOD FOR FUEL. The Farmer should obtain his year's stock of wood for fuel as early in the season as possible, and before the depth of snow in his woodlands renders it difficult to traverse them with a team.

A valuable paper, by the Hon. John Welles, republished in the *New England Farmer*, vol. i. page 529, from the Massachusetts Agricultural Repository, recommends cutting hard wood trees between 40 and 50 years of age; and the writer states that "though trees may shoot up in height by standing longer, yet the period of the most rapid vegetation is mostly over, and by that means much of the under growth is necessarily destroyed." Mr. Welles is of opinion that in cutting over a wood lot to obtain fuel, it is best to take the whole growth as you proceed. He observes that "we have been condemned as evincing a want of taste in cutting off our forests without leaving what it would take half a century to produce, a shade near where it is proposed to erect buildings. The fact is that trees of original growth have their roots mostly in the upper stratum of earth, and near the surface. A tree acts upon its roots and is acted upon by the wind, sustaining in common with the whole forest the force of this element, and it becomes accommodated or naturalized to its pressure. But when left alone or unsustained, it is borne down by the first gale, often to the injury of property and even of life." The *Farmer's Assistant* likewise says, "if woods are old and decaying the better way is to cut all off, as you want to use the wood, and let an entire new growth start up, which will grow more rapidly."

WARNING ROOMS. It is a very wasteful practice to burn wood in large open fire places, as is still the custom in many parts of the country where fuel is an important item of annual expenses. Stoves of various forms, and diversities of construction, are, however, gradually obtaining the preference, to the mode of consuming fuel adopted by our ancestors, when it was considered as an object of importance for a farmer to consume and destroy his fire wood and timber as fast as possible in order to expedite the clearing of land. The *Farmer's Assistant* gives the following mode of warning rooms, &c. which may be new to some of our readers, and, perhaps excite some who are possessed of what a *crainologist* would call the *organ of inventive ingenuity* to make further improvements.

"As it is essential to make a little fuel answer for this purpose, as well as for boiling, baking, roasting, &c. we will here describe a simple and cheap method for all these purposes; leaving every one to vary from it, by the use of stoves, or otherwise, as he may think proper."

"Make, of sheet-iron, something in the shape of a potash kettle, but not near so deep in proportion to its breadth on the rim, and let it be, say, two and a half feet in diameter across the rim; set it, bottom upward, on brick-work suitable to the dimensions of the rim, about ten inches high, leaving a place to fix an iron door, like the door of a common stove: Build a brick wall all round and over this, leaving a space between it and the sheet iron, of about two inches, and an opening where the door, just mentioned, is placed. Apertures are to be left in this outer wall, for inserting tubes for carrying off the air that is heated between the outer wall and the sheet iron, in different apartments."

"When a fire is made within the part covered by the sheet iron, the air between that and the outer wall becomes rarified, and of course ascends through the tubes into the different apartments or rooms, while the fresh air is constantly rushing in to supply its place.—Thus, while a constant current of cold air is rushing in below, a like current of warm air is carried off into the apartments where it is wanted. When any of these is sufficiently filled with warm air, the tubes leading into it are to be stopped in part, or wholly, till more heated air is wanted. It would be most advisable to let the heated air into each room in different places, in order to distribute it more equally."

"In a room warmed in the usual way, about two thirds of the whole heat of the fire passes out of the chimney. In the mean time, all the air in the room will also have passed off in that direction in less than an hour, and of course cold air must rush in to supply its place. Thus the whole air of such room has to be heated over again once an hour, and this is to be done with only a third of the heat afforded by the fire. Now, according to the plan here recommended, the air in a room would require a degree of heat equal to warming the whole over again, about once in six hours, as the heated air is not to be allowed to pass off out of a chimney: and for this purpose of heating, at least two thirds of the heat of a smaller fire can be applied.—Thus a room, to be warmed in the common way, requires a fire which gives twelve times the quantity of heat that is required in the method above described."

"This heating stove may be set in the kitchen; but a cellar-kitchen, or one lower than the dwelling-rooms, would be best. It may also be set in a small building adjoining the house; but let it be set lower than the rooms of the house."

"But, in order to render this complete, let the steam-cooking, baking, and roasting apparatus be attached to it. For this purpose, let the smoke and the heat that goes with it, pass out through the hole about four inches square, made in the side of a sheet iron, opposite the door; and let it be carried in a zigzag manner, back and forward, under the bottom of a boiler, made of sheet iron, and this will sufficiently heat the water in that to afford the requisite degree of steam for the vessels used for cooking by steam, as well as for heating water in adjoining wooden vessels of different sizes, to be used for different purposes. The pipe, conducting off the smoke, &c. after having passed under every part of the bottom of the boiler, is then to be carried upwards, and pass round three sides of a small oven, made of sheet iron, which is to be used for baking and roasting. The outside of the smoke-pipe, and of the door of the oven, should be thickly coated with powdered charcoal, in order to prevent the heat passing off through the exterior surface, until it shall have ascended above the oven."

"Thus, with one half of the fuel used in a kitchen fire place, every room, in a house of moderate size, may be warmed; all the culinary business may be performed; roots may be boiled for cattle in large vessels made for the purpose; and all this may be performed without half the risk from fires which attends the usual methods."

The building which contains the Boston Athenaeum, and other houses in this city are warmed by means similar to those above described.

Fatal Accident.—On the 12th inst. a young man by the name of Seth Smith, formerly of Pomfret, Vt. while driving a team, with a load of wood from Billerica to Boston, was killed by the wagon wheel passing over him.

FOREIGN.

Spanish America.—A late London Courier says "that all questions relating to the late Spanish settlements in South America, will become matter of discussion in a General Congress. Such at least is the tenor of the proposition made by France to our Government, but to which we have declined acceding. Whether this determination on our part may alter the original intention, is a point we cannot decide."

Turkish Atrocity.—A Greek priest named Chreben crucified by the Turks in mockery of his life.—He was after being several hours tortured in this manner, dashed with pitch and burnt alive.

Dreadful inundations occurred in the North of Italy and the Tyrol about the middle of October. Extensive devastations have been caused by long continued rains, and the destructive rising of several mountain streams. The city of Trent was several times in danger of being entirely destroyed, and fears were entertained as to the 13th as the rain continued to fall in torrents. The third part of the city of Verona was under water in many parts up to the first stories of the houses. Number of bridges were carried away in the Tyrol many lives lost.

Storms on the English Coast.—The London Courier of the 2d of November says, "our papers and advertisements this morning from all parts of the United Kingdom furnish a mass of calamitous details of the devastation by the tempestuous weather which prevailed during Tuesday and Friday last. To an extent of devastation of property is added a melancholy human life."

The London Courier states, that the Etoile, a French paper, printed at Paris, notices the fitting out of an armament at Cadix to assist the Royalists of Peru in recovering that fine country from the Revolutionists.

Gibraltar, Oct. 16.—We are crowded here with fugues from Cadiz, among whom are upwards of 1000 members of the Cortes. They are allowed the right of hospitality, but cannot remain in the garrison over days. They will probably seek an asylum in England.

DOMESTIC.

Cause of the Greeks.—A large and respectable meeting was held at Philadelphia on the evening of the 1st, to devise means to assist the Greeks, at the Bishop White presided. An address from the Greek people of the United States was read, and a committee was appointed to prepare resolutions for the consideration of the meeting, who proposed showing their relief.

Another coal mine.—We have been shown a mine of coal from a mine lately discovered on the western side in this town. The coal having been tried, is pronounced to be superior to the Lehigh or Lackawanna. It is softer, and kindles much easier. The mine has been excavated to the depth of seven feet, and proves good. Should the canal to connect the Hudson and Delaware rivers, be cut through this county, mine may prove a rich fund to the owners, as it is near the proposed route.—*Sullivan Whig.*

New mode of refining Salt.—Muriate of Soda common salt, may be refined by putting it into an alutary furnace, kilns, pots, pans, or other fit vessels, together with the necessary re-agents and matter, and exposing it to such a degree of heat as will melt it. It must be kept in fusion a sufficient time to decompose, separate or precipitate the metallic and impurities, and then drawn off as long as it runs pure, it must be suffered to cool.

Cotton.—The crops of cotton of 1832, and 1831, been estimated as follows—

New Orleans	bags 172,000
Mobile	50,000
Savannah	170,000
Charleston	160,000
N. Carolina and Virginia	43,000

Total of bags, 595,000. The increase of the last year is reckoned to be 73,000 bales.—*Nat. Register.*

Best Fabrics.—The Messrs. Morgans of New York, have commenced the Furniture and Printing business. One yard of their goods is as heavy as two of the imported, and will do the service; the colors are warranted and the fashionable.

re informed, that Benjamin Jourdan, of Putnam Co., has recently invented an instrument for the sun's meridian altitude, for accuracy and simplicity perhaps superior to any thing of the kind in use. A great accuracy has been ascertained in measuring the sun.—*Georgia Journal.*

terful Dispensation.—The Louisiana Advertiser, November 22, says, "We have been informed from several sources, and have reason to rely, to a extent, upon the correctness of the information, that the 21st of October, a sudden change of weather was experienced at Tampico and the vicinity, the thermometer falling 40 degrees during the day; the consequence of which was, that 500 died in one night, in that city and the adjacencies. One of our United States' vessels was at the time, and our informant adds, that she lost the same time, 13 persons, including several

gement in Tanning.—The Baltimore Gleaner, says, "Dr. H. H. Hayden, of that city, has discovered a very important improvement in the process of converting raw hides into leather, by the use of a pyrologeneous preparation, the use of which has secured by letters patent, under the name of the United States."

This method, raw hides, of any description, after the process of *hairing and bating*, are converted into leather in less than **THIRTY-SIX HOURS.**
Hamden Journal

ing Fire.—On the night or the 5th inst. at 10 o'clock, (Conn.) the dwelling house of Rev. Sant. with all its contents, was consumed by fire—between 2 and 3,000 dollars. Mr. M. was not at home, his son's wife who had not left the house for several days, with 6 children, and two in her arms, narrowly escaped, without an article of clothing.—*ibid.*

John Brown of Pittstown, Pa. was found dead at his side, some time since, supposed in consequence of the lock jaw, having been bitten by a dog the evening before.

of Washington.—More than \$13,000 have been subscribed to the Treasury of Virginia by subscribers to the erection of a Monument to the memory of the illustrious Washington.

at bridled not her tongue," shall pay five dollars! A lady, by the name of Mary Patterson, sentenced to pay five thousand dollars at New York, Pa. for slandering the character of Mr. Wall.—*National Gazette.*

elling house, owned and occupied by the late John Fisk, of Swanton, Vt. was consumed by fire on Sunday week. The furniture and other articles belonging to it, were saved. The loss is said to be \$500.

CONGRESSIONAL.

Monday Dec. 3. Several messages were received from the President on executive business in relation to the adjustment and settlement of accounts of Daniel D. Tompkins, late Governor of New York, allowed by the Accounting Officers of the Treasury subject to the revision and final decision of the President. The balance allowed is \$35,193. Subject to the consideration of Congress.

ment for Debt.—On motion of Mr. Johnson a resolution was ordered to be appointed to consider the expediency of abolishing imprisonment for debt.

The President *pro tem* announced the appointment of the usual Committees. Mr. Benton gave notice that he should ask leave to introduce an amendment to the Constitution, so as to provide that the election of President, &c. shall be made by the people, without the intervention of Electors.

Mr. Johnson of Kentucky, offered a resolution relative to the expediency of constituting three additional Judicial Circuits; one to be composed of the states of Tennessee and Alabama; one of Mississippi and Louisiana; and one of Indiana, Illinois, and Missouri.

Dec. 11. Mr. Holmes, of Maine, submitted a motion which had for its object the preventing of frauds on the revenue on the eastern frontier of the United States.

Mr. Barbour introduced a resolution for dividing each state in the U. S. into Districts for the purpose of electing the President and Vice President of the U. States.

IN THE HOUSE.—Monday, Dec. 3. Mr. Webster of Mass. submitted for consideration the following:—

"Resolved, That provision ought to be made by law, for defraying the expense incident to the appointment of an Agent, or Commissioner to Greece, whenever the President shall deem it expedient to make such appointments."

This resolution Mr. Webster, supported by some pertinent remarks in which he expressed a hope "that we should show to the world that there is at least one Government which does entertain a proper view of that barbarous despotism, which under the eyes of Europe, has been permitted, by a system of the foulest atrocity, to attempt to crush that interesting christian nation." On motion of Mr. W. the resolution was ordered to lie on the table.

On motion of Mr. Cambreleng, the Committee on Naval Affairs was instructed to inquire into the expediency of continuing pensions to widows or orphans of officers, seamen or mariners slain in the service of the United States, &c.

Dec. 9. Mr. Sibley of Mass. presented a memorial from Norfolk District, Mass. contesting the validity of the seat of John Bailey in the House, who, when elected was, and had been for some years before, a Clerk, in the department of State in Washington.

Mr. Webster presented a memorial from Boston, praying for a duty of 12 1/2 per cent. to be imposed on imported Woollens.

Mr. Plumer of N. H. moved, That the Committee on the Judiciary be instructed to inquire into the expediency of allowing costs in cases where damages may be recovered for the violation of the rights of patentees under the several acts concerning the issuing of patents for useful discoveries and inventions. *Adopted.*

Dec. 10. Mr. McLane, of Delaware, submitted a resolution for requesting information from the President touching the Florida Treaty, &c.

Mr. Hemphill submitted a resolution for requesting information from the President relative to French spoliation on our commerce.

Roads and Canals.—On motion of Mr. Standier, the Committee on Canals was instructed to inquire into the expediency of making appropriations for opening a Canal between the navigable waters of Tennessee and Coosy rivers.

Dec. 11. The resolution of Mr. Hemphill, on the subject of French spoliation was agreed to.

Nova Scotia Potatoes.—On motion of Mr. Kidder of Maine, the Committee on Commerce was instructed to inquire into the expediency of imposing a specific duty on potatoes, imported from Nova Scotia, Ireland, and all other foreign countries.

Manufacturers' Marks.—On motion of Mr. Breck, the Committee on Manufactures was instructed to report on the expediency of providing by law against counterfeiting such marks or names as the manufacturer of any kind of Ware may see proper to write or stamp thereon.

Vice President's Accounts.—The House in Committee—considered the bill appropriating \$35,000 for the relief of Daniel D. Tompkins, and a long debate ensued in which the bill was opposed by Mr. Cocke of Tennessee. Mr. Livermore, of N. H. and supported by Mr. Cambreleng and Mr. Wood, of N. Y., Mr. McLane of Del., Mr. Clay and Mr. Trimble of Kentucky. The question was then taken, and Mr. Cocke's motion for rejecting the claim was negatived by a decided majority.

SUBSCRIBERS indebted for the first volume of the Farmer, are earnestly requested to make immediate payment at this office. The sum due from each is small, but the aggregate amounts to a large sum, and unless received soon, the subscriber will suffer very serious inconvenience in consequence.

Nov. 29, 1823.

THOMAS W. SHEPARD.

A New and Valuable Improved Implement

JUST completed and for sale at the AGRICULTURAL ESTABLISHMENT, No. 20, Merchants Row, Boston, an improved *Straw Cutting Machine*, which from its plain and simple construction is very effective in its operation, and is a great improvement on the various machines invented for this purpose; the power being applied in such a manner as to greatly increase the operation of the machine and places the workman in so convenient a position, as to enable him to tend and work with perfect ease and convenience to himself and so timed as to cut any length of fodder required.

BY THE REV. G. CROLY.

What is death? 'Tis to be free?
No more to love, or hope or fear—
To join the great equality:
All alike are humbled there!
The mighty grave
Wraps lord and slave.
Nor pride nor poverty dare come
Within that refuge house, the tomb!

Spirit with the drooping wing,
And the ever-weeping eye,
Thou of all earth's kings art king!
Empires at thy footstool lie!
Beneath thee strew'd,
Their multitude
Sink like waves upon the shore!
Storms shall never rouse them more!

What's the grandeur of the earth
To the grandeur round thy throne?
Riches, glory, beauty, birth,
To thy kingdom all have gone.
Before thee stand
The wondrous band;
Bards, heroes, sages, side by side,
Who darken'd nations when they died!

Earth has hosts; but thou canst show
Many a million for her one,
Through thy gates the mortal flow,
Has for countless years roll'd on:
Back from the tomb
No step has come;
There fix'd, till the last thunder's sound
Shall bid thy prisoners be unbound!

TRANSLATION OF A FRENCH EPITAPH.

A glutton renowned
Lies under this ground,
Who forever to eating was prone;
Before his last breath,
He'd e'en have eat Death,
But of him he found nothing but bone.

MISCELLANY.

ANECDOTES.

A Ghost.—A foolish fellow went to the parson of the parish, and making up a very long face, told him he had seen a ghost, as he was passing by a grave yard, moving along against the side of the wall. "In what shape did it appear?" "In the shape of an ass." "Go home and hold your tongue about it," said the parson, "you are a very timid man, and have been frightened by your own shadow."

The Undertaker.—An undertaker was observed to shed tears at the interment of a quack. A friend asked him the cause of it. "Why," said he, "you see I have just buried one of my best friends."

A Grave Digger's Bill.—A grave digger, who had buried Mr. Button, sent the following bill to his widow:—"To making a Button-hole, 2s."

Remedy for Short Blankets.—An Irishman who was sent on board of a ship, and who believed in ghosts, inquired of his messmates if the ship was haunted. "As full of ghosts as a church-yard," replied they, "they are ten thousand

strong every night." This so terrified Pat, that whenever he turned into his hammock, he pulled his blanket over his head and face, so that from his knees downwards he was always naked and cold. "That there purser's a terrible rogue! he serves out blankets that don't fit a man; they are too long at top, and too short at bottom, for they cover my head and ears, and my feet are always perishing with cold. I have cut several pieces off the top and sewed on the bottom, but it don't make it a bit longer."

Some tradesmen the other evening, at a club in Westminster, were discussing the political topics of the day, and among other subjects touched upon the Holy Allies. "They are a blessed trio," said one of them, "and I esteem them so highly, that were they to come over here. I would most willingly work for them for nothing." "Indeed!" said one of the company. "What trade are you my good friend?"—"A ropemaker," replied the other.—*Portsmouth Journal.*

When Dr. Limmerman was at the court of Berlin, Frederic II. asked him one day in conversation, if he could ascertain how many he had killed in the course of his practice. "That is an arduous task," replied the doctor, "but I think I may venture to say, not half so many as your majesty."

There are half a million of scholars at the public schools throughout the U. S.; and more than three thousand students at the colleges which confer degrees.

There are about ten thousand physicians and upwards of ten thousand lawyers.

There are about nine thousand places of worship, and five thousand clergymen.

About four thousand and four hundred patents have been taken out for new and useful inventions, discoveries and improvements in the arts.

Between two and three millions of dollars worth of books are annually published in the U. States.

A thousand newspapers are published.—There are more than one hundred steam-boats, comprising more than fourteen thousand tons, navigating the Mississippi.

The vessels of the U. S. by sea, perform their voyages on an average in one third less than the English.

There are five thousand post offices, and eighty thousand miles of post roads, and twelve thousand miles of turnpike roads.

There are three thousand legislators.—There are two hundred printed volumes of law reports.

Domestic Invention.—We were favored, a few days since with the inspection of an invention for fastening window blinds both when they are open and when they are shut. It will supersede the hasps, usually attached to blinds, and the awkward looking iron cross now used to keep them open. It is a very simple piece of workmanship, being merely an iron three inches in length attached to the bottom of the blind, having in a hook at each end somewhat resembling the catch to a common iron thumb-latch, and a short iron hook driven into the house to receive the catch and hold the blind open, and another in the bottom of the window frame to

hold it shut. The iron on the blind is kept its place by a spiral wire spring which matches the hook and fastens the blind when the open or shut, without our taking the trouble to reach out and make it fast with the hand. A great advantage of this invention is, that it relieves us from the dismal groans of our old blinds, when the winds blow and rage around us. For it fastens the blind perfectly tight, so that it can neither blow off hinges nor make any noise by its motions.

Mr. THOMPSON BACON, of Bedford, the author of this invention, intends to apply to Congress during the present session for a patent, and then offer these fasteners for sale. They will be only *forty cents* for each window, and the strength of the machine is such that it will last as long as a house. We think this much preferable to any thing else of the kind we have seen, and hope soon to find it in common.

[Concord Gazette.]

A strange Animal.—A few weeks since a wild and ferocious animal of the Cat kind, was killed by some hunters in Loudoun Co. Va. Its coat was a reddish brown, and its ears and the tip of its tail very black. It measured from nose to the end of its tail 6 feet 9 inches; weighed 95 pounds, and was 31 inches in height. Its head resembled a cat's and was nine inches across the forehead.

"In regard to the manner of taking this vagabond of the forest, (says the editor of the *Hanover Free Press*) we have heard several tales. The one most to be depended on we believe is this; that the animal having been discovered by Mr. Donaldson's hounds, Mr. Donaldson, approached the spot where it was found that it advanced towards him in a haughty way. He retreated and summoned to his assistance a party of neighbors, who it seemed, assembled for the purpose of having a fox hunt. Among them was Mr. Christian Miller, who had a large bull dog, which was set upon the animal, and seized it by the throat; it immediately turned upon its adversary, and catching by the nose, would soon have dispatched had not a negro man of Mr. Miller's, seeing the danger of his favorite, and heedless of his own peril, rushed forward to his relief, and gave the animal a well aimed blow on the head which deprived it of life, and thus averted dangers which threatened more than one party."—*Poult. Adv.*

Nearly thirty thousand men are at present employed on the great Canal from the Texel to Amsterdam. The marshy earth which is taken towards the bottom of the Canal, is taken out with bag-nets, and fills more than a thousand boats each day. The Canal will be five feet in depth, so that the largest East India man, may pass direct to Amsterdam without unloading part of their cargoes at the Scheldt. The Canal will be more than 60 English miles long, and will cost, without including great flood gates, more than 90 million guilders.

TERMS OF THE FARMER.

and Observations relating to Agriculture and Domestic Economy.

[BY THE EDITOR.]

THE USE OF SALT AS A MANURE. There exists a great difference of opinion with regard to the use of common salt as a fertilizer of soil. Some writers on the subject contend that it is very beneficial, but others assert that its use is attended with little, if any advantage. Some are of the opinion that its application in considerable quantities results in barrenness. A small quantity, it is said, accelerates putrefaction, and is known that a large quantity prevents the putrefactive process. We shall offer to our readers the opinions of the apparently contradictory facts of opinion of eminent philosophers and agriculturists on this topic, and conclude with some attempts to reconcile them, together with conditions which appear to us to be of importance in the use of this article as a manure.

In the early ages of the world, salt was regarded as the emblem of utter barrenness and sterility. And we read in Sacred Writings of the people, who to satiate their vengeance against their enemies, sowed grounds with salt to render them unfit for cultivation. (See Deut. xxix. 17. Judges ix. 45. Zeph. ii. 9.) Virgil in his Georgics, lib. ii. condemns a salt soil, as occasioning the degeneracy of fruit trees, and admitting of no amelioration from ploughing.

"The earth and bitter are not fit to sow
Will be tam'd and mended by the plough,
And grapes degenerate there, and imits decline
In their sweet flavours taste renounce their kind."
Dryden's Translation.

Speaking of fossil-salt, affirms that even in which it is found is barren, and unproductive of vegetation. And Plutarch observes that the Egyptians believed salt to be the spittle of the god Typhon, the great enemy of mankind; and hence he adds, they held it in abhorrence.*

Not only the ancients but many of our modern practical agriculturists have given opinions in favor of salt as a manure. In a paper, published in the "Memoirs of the Philadelphia Agricultural Society," page 177, by Hon. Richard Peters, the author observes "I have, in the early part of the season, [1810] spread salt in the way, the quantities recommended by Mr. Elliot on every species of crop, both of grass and grain. We have had an unfavorable spring, and to the long drought. I have perceived no effect good or bad, from all or any of the applications of salt. On my wheat I had some appearance of benefit, but it was not decidedly so. In another volume of the same work, the author observes, "It yet remains doubtful whether common salt is, or is not a manure, in

Rees's Cyclopaedia, Art. Salt.

The mode of applying it was to mix one bushel with two bushels of virgin mould where the grass had lain and rotted, or from marshy land or from ashes. The compound dry and friable. The three pecks of salt mixed in the compound so facilitate the strewing of it evenly. The time of application before vegetation begins in the spring,

its crude state. I have sometimes thought well of it; and used it every way. When mixed with putrescent substances judiciously, it is best. In large quantities it prevents, though in small portions it promotes putrefaction; being antiseptic in one case, and septic in the other. Lord Dundonald decides against the use of salt, especially on poor land: he says if it be at all useful it is on rich lands. He highly recommends sea-water for its great benefits in husbandry. It contains in a ton a bushel, or a bushel and an half of salt. Sea salt is recommended for the destruction and putrefaction of snails, slugs, grubs, worms and insects infesting grounds. They abound most in lands to which animal manures have been long applied. The vitriolic acid is equally efficacious; and I have therefore believed they do not much infest plastered fields."

Dr. Deane observed that "salt is of essential importance to the farmer as a manure. It may be applied to the soil, either by itself, or mixed and dissolved in compost. In the latter method I have found it to be a good fertilizer of land.

"But if salt be applied unmixed and undissolved, it will endanger the existence of tender plants.

"In June, 1786, I salted one bed of my onions, one bed of my carrots, and one bed of my early turnips; laying the salt under the surface, in the centres of the intervals, between the rows; at some distance, perhaps six inches from the plants, that the salt might have time to be dissolved and altered, before the fibrous roots should reach it. The carrots of the salted bed, evidently grew much larger and better than the rest of the carrots; but I could not perceive that the salt was at all beneficial to the onions or to the turnips.

"According to Mr. Ford's experiment in salting flax-ground, salt seems to be highly beneficial to that crop. He spreads the salt over the ground at the time of sowing the seed; and thinks that the quantity of salt should be double that of the seed. From three acres in flax salted, he had fifty bushels of seed, and an excellent crop of flax. It was thought that the advantage of salting appeared more in the seed than in the harle.

"Mr. Elliot speaks of five bushels of salt being applied to one acre of flax, which is a much larger proportion, and that it had an extraordinary effect; and also of a great crop of wheat being increased by salt."

The Farmer's Assistant says, "An intelligent Farmer once observed to us, that during our revolutionary war, when this article was so dear that he could not afford to give it to his cattle, his barn dung seemed to be of little service to his lands; but that he found the case much altered when he could again afford to deal out a sufficiency of it to his stock."

Sir Humphrey Davy says "when common salt acts as a manure, it is probably by entering into the composition of the plant in the same manner as gypsum, phosphate of lime, and the alkalies. Sir John Pringle has stated, that salt

in small quantities assists the decomposition of animal and vegetable matter. This circumstance may render it useful in certain soils. Common salt likewise is offensive to insects. That in small quantities it is sometimes a useful manure. I believe is fully proved; and its efficacy depends on many combined causes.

"Some persons have argued against the employment of salt; because when used in large quantities, it either does no good, or renders the ground sterile; but this is a very unfair mode of reasoning. That salt in large quantities rendered land barren was known long before any records of agricultural science existed. We read in the Scriptures that Abimelech took the city of Shechem, "and beat down the city, and sowed it with salt;" that the soil might be forever unfruitful. Virgil reprobates a salt soil; and Pliny, though he recommends giving salt to cattle, yet affirms, that when strewed over land it renders it barren. But these are not arguments against a proper application of it. Refuse salt in Cornwall, which, however, likewise contains some of the oil and exuviae of the fish, has long been known as an admirable manure. And the Cheshire farmers contend for the benefit of the peculiar produce of their country.

"It is not unlikely that the same causes influence the effects of salt, as those which act in modifying the operation of gypsum. Most lands in this Island, particularly those near the sea, probably contain a sufficient quantity of salt for all the purposes of vegetation; and in such cases the supply of it to the soil will not only be useless, but may be injurious. In great storms the spray of the sea has been carried more than fifty miles from the shore, so that from this source salt is often supplied to the soil. I have found salt in all the sand stone rocks that I have examined, and it must exist in the soil derived from these rocks. It is a constituent likewise of almost every kind of animal and vegetable manure."

Sir John Sinclair observes that "sea-salt properly applied acts as a manure. It is particularly useful when mixed with a dung hill, or strewed over farm-yard manures, at the time when they are carried into the field. In Cheshire, refuse salt is found to be a most excellent manure for pasture land or fallows. By the application of only eight bushels per acre, in the month of October, on some rushy land, a most flourishing crop of rich grass appeared in the month of May. Mixed with couch-grass and other rubbish, and afterwards with other manure, it produced the most beneficial effects in a crop of barley, and on grass lands.

"In a series of experiments by the Rev. Dr. Cartwright with salt he found a mixture of salt and soot preferable to any other manure: a circumstance which might be attended with considerable advantages to farmers in the vicinity of large towns.

"It has been ascertained in America, and confirmed by the experiments of Mr. Lee of Endfield Wash, near London that salt is an excellent

* Elements of Agricultural Chemistry. Phil. Ed. p. 301, 302.

manure for flax. The quantity of salt should be double that of the seed used, and at the same time. It is probable that all oily seeds should be treated in the same manner.

"But the most important circumstance is the beneficial effects of salt, in preventing mildew. In the course of a most extensive inquiry into the causes of that disease in wheat, and the means of its prevention, it appeared that a farmer in Cornwall was accustomed to manure his turnip land with the refuse salt from the pitchard fishery; and that ground thus treated was never liable to mildew, though it infested all the neighborhood. This is a hint, which may prove of incalculable value, if in all cases it should prove equally effectual."

The Farmer's Journal, an English paper, states, in opposition to the theory, that salt will prevent mildew that a correspondent of the Editor had tried an experiment by sprinkling salt water on a small patch of wheat "but it had no effect in preventing the progress of the disease, and eventually the straw became quite black."

See *New England Farmer*, vol. i. page 143.

(TO BE CONTINUED.)

Massachusetts Agricultural Society.

FOR THE NEW ENGLAND FARMER.

REPORT No. IX.

The Committee on Agricultural Experiments submit for the consideration of the Board of Trustees the following, in addition to their Report dated the 16th of October last, to wit:

That Col. Joseph Valentine, of Hopkinton, in the County of Middlesex, is entitled to the Society's premium of \$30, for having raised the greatest quantity of Indian Corn, being 127 bushels and 29-32 of a bushel, on one acre of land. Col. Valentine's description of his culture is as follows:—"The quality of the soil is a deep yellow loam, situated on a western declivity, and naturally moist. The land has been improved for mowing six years last past, and until the last year it has yielded very heavy crops. In July, 1822, the crop of hay falling below the produce of former years, I thought it expedient to stir the ground; in August following the ground was broken up, and in November it was harrowed, and cross ploughed. In the spring of 1823, it was again ploughed, and harrowed, and twenty loads of green barn manure spread equally over it, and ploughed in. It was then furrowed in rows about three feet and six inches apart, with a large horse plough, the plough going twice in each row to make a deep channel for depositing the compost manure, and also to leave the seed when planted lower than the general surface of the ground. The rows thus prepared, were filled with twenty loads of barn, hog-yard, and night manure, well mixed, and pulverized with Smithfield lime; the manure was then levelled, and the kernels of seed placed about ten inches apart widthwise, and four inches lengthwise in the row, and covered lightly with fine mould. The seed was the yellow twelve rowed corn, which was soaked in a strong salt petre brine twenty-four hours, and then spread, sprinkled with quick lime and raked over until completely coated with lime—it was ploughed twice, and hoed three times at the last hoeing, the first of July, the suckers were pulled out, and in the fore part of August the suckers were again pulled out, and the false stalks cut away.

In hoeing the corn I was particularly careful to loosen the soil and remove the weeds without raising the earth about the stalks, as I had usually done—the stalks would average from nine to ten feet high, and were cut the first week in September. The first week in October the corn was harvested, and carefully measured in baskets by two of my men who had assisted in cultivating the crop. I directed the same men to take each of them a basket and fill it with ears in the same manner as when they measured the whole, and to shell and measure the quantity of shelled corn obtained from a basket of ears; the amount of shelled corn from each basket of ears was the same, viz., nineteen quarts; and when turned together and measured the result was one bushel and six quarts and a fraction over, from the two baskets. By computing the produce of the whole acre from the quantity of ears as measured in the basket, and the amount of shelled corn contained in a basket of ears, the result will be one hundred and twenty-seven bushels and twenty-nine quarts of shelled corn, weighing between sixty and sixty-two pounds to the bushel. The field in which the above acre was measured contains three acres; one half of which was planted with seed prepared as above stated; the other half was planted with seed prepared in its natural state. The corn in every part of the field came up well; and as the ground was all manured and cultivated alike, there could be no difference in the quality of the soil, to invite or repel insects and vermin. But in that part, which was planted with seed in its natural state, at least one sixth part of the blades were eaten off and destroyed by the worms, while in the part planted with seed soaked in brine and coated with lime, not a single blade was discovered that had been attacked by them. This is the first experiment I ever attempted to prove the utility of securing corn against the ravages of the worm by any process applied to the seed. Perhaps the mode above described and pursued by me, may not always be attended with the like success. It may, however, be the means of exciting the attention of others who have more leisure and ability than myself to discover and apply a certain remedy for so great a hindrance to the farmer. The value of the stalks and fodder I consider equal to one ton and a half of English hay—the entire expense of cultivating this acre of corn, including thirty dollars for the 40 cart loads of manure was fifty-five dollars and seventy-five cents." Col. Valentine is also entitled to the premium of \$20, for having raised the greatest quantity of wheat, being thirty-seven bushels and one fourth of a bushel on one acre. "In the spring of 1822, it was ploughed and planted with Indian corn, forty loads of manure were spread and laid upon it, and the crop produced was one hundred and sixteen bushels and twenty-eight quarts of corn, well dried and fit for use. In the spring of 1823, as soon as the ground was fit for ploughing, I had it ploughed twice and harrowed; three bushels of Gilman wheat were sowed on one acre and a few rods, and ploughed in; I then sowed twelve pounds of clover, and half a bushel of herds grass seed, spread one hoghead of slacked lime upon the land, and harrowed it well twice with an iron harrow. The wheat before sowing was washed clean in clear water, then soaked forty-eight hours in strong lime water, then laid on a dry floor and slacked lime

sprinkled upon it, and frequently stirred until it was covered with lime. Such was my practice with the seed. In the month of July I employed a Surveyor to measure the land on which the three bushels of wheat were sowed, a found it to contain one acre and a few rods over—the number of rods exceeding one acre was stalked off, and the wheat growing thereon was reaped and threshed by itself; the produce was between one and two bushels—the acre was reaped and bound with long rye-straw, and found to be seven hundred and sixty-two bundles making fifty shocks and twelve sheaves; when threshed, winnowed and measured, the produce of the acre was found to be thirty-seven bushels and one fourth of a bushel—the quality of the grain was excellent, not a kernel of snout or bur grain could be found, and the straw was perfectly clear and bright; the kernel was very large and full. Many persons have examined it who have been acquainted with the culture of wheat in the western country, and they pronounce it equal to the produce of the new large growth—its weight is sixty pounds to the bushel.

That Silas Pearson, of Newbury, in the County of Essex, is entitled to the Society's premium of \$20, for having raised the greatest quantity of Barley, being fifty-two bushels and eighteen quarts upon one acre of land. "The entire lot contains one acre and fifty-three rods; the soil is a gravelly loam; in 1822, it was planted with potatoes, and manured with about twenty cart loads of compost manure to the acre, which produced a handsome crop—in April, 1823, it was ploughed plain and harrowed, the seed was then sowed and covered with a harrow which took four bushels of the two rowed kind; the crop was mowed and threshed out in August and the amount was seventy bushels, at fifty pounds per bushel."

That John Prince, Esq. of Roxbury, is entitled to the Society's premium of \$20, for having raised the greatest quantity of Mangel Wurtzel, being 762½ bushels, on one acre. "The land was cultivated in 1822 with corn, potatoes, and winter squashes, in alternate rows, and 16 or 18 cart loads of compost manure (one half manure and mud) to the acre;—it is almost on the top of my hill, is gravelly loam, or a hard pan bottom inclining to the S. S. E.; this season 24 cart loads of the same kind of compost manure were spread on the whole flat, and ploughed in, the harrowed flat, and a common marker made five furrows about two inches deep, and two feet apart, the seed was dropped about 5 or 6 inches apart, and covered up on the third of May, from the 11th to the 16th of June, they were hand hoed, weeded, and thinned out to 10 or 12 inches apart—on the 1st of July a second and last hoeing and weeding—in August and September were too thick, some were drawn for hogs—and in October, by measurement, one hundred and twenty bushels were drawn on one end of the field;—and on the 4th and 5th of November the whole crop was drawn and carted to the barn cellar, and part were pitted in the field, as described in the Massachusetts Agricultural Repository, No. 3. vol. vi. particularly by those intended for seed the next season. Eight rows on one side, and the whole length of the field, was the sugar beet, from seed I imported two years since from France, and am much pleased with them; I think they produce fully as much as the mangel wurtzel, weigh 5 or 6

Highway Robbery.—Rufus G. Amory, Esq. of Boston, was robbed near New Brunswick, in N. Jersey on the evening of the 16th inst. Mr. A. was attacked by two foot pads, bound to a tree, and robbed of \$470, his horse, a valuable gold watch and a part of his clothes. Mr. A. succeeded in unloosing the cords, which bound him and reached a house in safety.

An Address of the Trustees of the "Gardiner Lyceum."

Ten months have passed since the Gardiner Lyceum commenced its operations. Its success, considering the novelty of its plan, has not been small, and the Trustees regard it as an earnest of success, equal to their warmest anticipations, when the plan shall have become more fully and generally understood.

An address was circulated about a year ago, giving some account of the plan, and as that address has excited an extensive interest to see a fuller development of it, it is thought expedient to publish another, in which can be given the result of more mature deliberation, and of some experience.

The whole course, it will be recollected, was fixed at three years. Students are not required to remain during the whole of this period, but can leave at any time, when their circumstances shall render it expedient. They can likewise be admitted at any time, provided they are qualified to enter one of the existing classes, and in the examination of candidates for an advanced standing, such studies will not be insisted on, as are not necessary to pursuing the subsequent parts of the course. Occasionally persons may be permitted to join a class in a particular study, as chemistry, e. g. without having gone over the preceding parts of the course, if they give evidence of other sufficient qualifications.

The studies of the first year will be the same for all; after which, they will be varied, if necessary, to accommodate the wants of individuals. No studies, however, will be pursued at the Lyceum, which will not be profitable for all of those classes of citizens, for whose accommodation it is established.

The first year is devoted chiefly to Elementary Mathematics, which form a proper foundation for the course of study, from the very many and important relations, which they have to the Arts and Sciences, and from their furnishing, in an eminent degree, that mental discipline, which is more than half the object of every system of education. The mathematics, used at present, comprehend most of the course, which has recently been selected and translated from the works of the most eminent French mathematicians, for the use of the students at the University at Cambridge.

The following is the arrangement of the studies.

THIRD CLASS.

Geography, including the study of maps and globes.

Arithmetic, which has been hitherto pursued with Colburn's Sequel as a text book, but hereafter the Arithmetic of Lacroix will be used in consequence of its connexion with the succeeding parts of the course.

Book-keeping, which is to every man in business of the highest consequence, and to every one important.

These studies will take up the first term.—During the second, will be studied

Algebra; a science, which is useful in a high degree, as it furnishes demonstrations of the most important rules of Arithmetic, and gives the means of solving many useful questions, which are beyond the reach of Common Arithmetic. Its conclusions derive great value from this consideration also, that they are general,

and the solution of any particular problem gives not only the individual result sought for, but a rule, expressed in the best possible way for solving directly all other problems of the same kind. Algebra is absolutely necessary to those, who would make any attainments in the higher Mathematics and Mechanics, as it is the introduction to all the Analytical Sciences.

Legendre's Geometry, and the *Trigonometry of Lacroix*. These sciences are the foundations upon which rest the Mensurations of Superficies and Solids; of Heights and Distances; and of all the Calculations of the Surveyor, the Navigator, and the Astronomer.

These studies will occupy the second term, and be continued in the third, till finished.

Besides these, in the third term, Blair's Rhetoric abridged, will be taught, and the Studies of the year reviewed.

Through the whole year, there are recitations on Monday morning in Scripture history, and exercises in reading and English grammar.

SECOND CLASS.

FIRST TERM.—*Bezout's Application of Algebra to Geometry*, and the *Application of Trigonometry to Surveying and Navigation*.

Chemistry, which teaches those laws of nature which lie at the foundation of many of the most important arts of life.

Hedge's Logic.

The studies of the second term will embrace *Mechanics*;

Smellie's Philosophy of Natural History.

Darby's Agricultural Chemistry may here be studied by those, who intend to devote themselves to Agriculture, and others, whose pursuits in life, may have other relations with Chemistry, will pursue their studies in books suited to their object, as, for instance, the future dyer, will study such works as Bancroft's Philosophical Treatise on Colors, and Cooper's on Dyeing.

Those who wish to qualify themselves for practical Surveying, will be instructed to perform actual surveys, for which the Lyceum is amply furnished with instruments; and nautical calculations and observations and the use of nautical instruments will be taught to the intended navigator. Those, who would qualify themselves for millwrights, or for any of the departments of Engineering, will here be directed into a course, especially adapted to their object.

The studies of the third term will include, *Hydrostatics and Pneumatics*, or the laws of fluids elastic and non-elastic.

Review the studies of the year.

Beside the studies above mentioned, there will be regular exercises in English composition, and Monday morning recitations in Paley's *Natural Theology*.

FIRST CLASS.

FIRST TERM.—*Natural Philosophy*.

Smellie's Philosophy of Natural History, finished.

Stewart's Philosophy of the Mind, vol. I.

SECOND TERM.—*Natural Philosophy*. *Conversations on Political Economy*.

Stewart's first vol. concluded.

THIRD TERM.—Collection of Essays, under the title of the *Federalist*, written by Mr. Madison, Mr. Hamilton and Mr. Jay, in defence of the American Constitution.

Review of the studies of the year.

Through the year, Monday morning recitations from Paley's *Evidences of Christianity*, and exercises in English composition.

As some knowledge of *Fluxions* is necessary to those, who wish to pursue their studies extensively in the higher Mechanics, to such will be taught in continuation of the mathematical course.

Such works as Stewart's *Philosophy*, *Conversations on Political Economy*, and the *Federalist*, are introduced into the last year of the course, from a conviction, that no study can be more important to man, than that of himself and of that part of his nature especially, which distinguishes him from inferior animals;—that it is important to every citizen of a free government, to have some knowledge of the principles of political economy;—and that to every American it must be interesting to study under the guidance of some of its ablest defenders, that constitution which binds together the former Colonies of a foreign power, and has consolidated them into a great and independent nation.

It will be seen at once, from the remarks above made, that the course which will be pursued, cannot be minutely detailed, as it must often be subject to variations, from the necessities of students, arising from the nature of the object they have in view and the pursuit for which they wish to be qualified. These objects and destined pursuits of the students will ever be attended to, and no one will be obliged to study that, which will not be of material service to him. The Farmer will not be put upon studies, which are important only to the Mechanic, nor the latter upon those which are of peculiar interest only to the former. This separation of studies, and the distribution of them according to the wants of the students, will be carried into effect, as far as the existing state of the institution will admit. Regularly however, and system will be preserved as far as possible. When there are several, who are under the necessity of leaving the common course, and their studies take the same direction, they will form a class, and if a suitable text book can be found, recitations will be had as usual. But in most cases, particular studies, such as the application of Chemistry to the individual Arts, will be pursued by one or two only, and suitable books for recitation can rarely be had. Such Students must pursue such a course of reading as will be pointed out to them, and will be assisted by frequent examinations, and Explanations, and will have when necessary the liberty of privately experimenting. This course of separate instruction will be often necessary in the applications of Mathematics and Chemistry.

Beside the recitations, it is intended to have two full courses of Lectures to the two first classes. The following hints of them, are given, to show their nature, and the subjects they will embrace. These lectures will not be confined to the students, but will be open to all, who may wish to attend.

1. CHEMICAL COURSE, which will include,
 1. A course on the principles of *Chemical Science*, together with such subjects as are usually introduced into a chemical course.
 2. Lectures on *Agricultural Chemistry*, in which will be considered the organization and

mineral constitution of plants; the phenomena of vegetation; the constituent parts and analysis of soils, and their improvement; manures, vegetable, animal, and mineral; the use of sowing and fallowing, and other agricultural acts connected with chemistry.

Lectures on *Dyeing*, in which the nature and preparation of Colors, and the use of mordants will be explained, &c.

These will be followed by lectures on *bleaching*:—on the manufactory of *pottery and porcelain*, with their *glazings*, &c.:—on the preparation of *cements*:—on *tanning*:—the manufactory of *oil and pearl ashes*:—of *glass*:—and on those mechanical arts, connected with chemistry, which are most practiced, and of the great importance.

II. MECHANICAL COURSE.

Statics; the mechanical powers; the doctrine of *collision* of bodies, and the vibration of pendulums; the maximum effect of machines, other subjects belonging to common mechanics.

Mechanical agents; the elementary parts of construction of machines; the regulation of machinery; friction.

Dynamics; which treats of the action of forces, when they give rise to motion.

Hydrostatics and hydraulics; water wheels and other hydraulic machinery.

Mechanical properties of air, and other elastic fluids; pneumatical engines; pump engines.

Description of some of the most important principles with the theory of their operations. Properties; strength of timber and other materials; equilibrium of arches; civil architecture.

Mechanical principles, upon which agricultural implements are constructed.

Besides the above, a course on Mineralogy is contemplated, which will embrace such parts of science as are of greatest practical value.

The extensive importance of minerals in forming manures, paints, and glazings for wares, their use in dyeing and a thousand other uses, render some knowledge of mineralogy very important in a country, which will doubtless prove rich in mineral treasures.

A short course will also be given on the different branches of experimental philosophy, Magnetism, Electricity and Optics, and upon Acoustics.

The Trustees have been always desirous of having a farm connected with the institution, in which the students, whilst enjoying salutary exercise, might practically acquire such a knowledge of agriculture, as would be of use to them throughout life, and at the same time, enable them in an honorable way, to discharge, by their own exertions, part of the expenses of the board. This object they hope soon to be able to accomplish. A donation of a small valuable piece of land, has recently been made to the institution near the Lyceum, well adapted to agricultural experiments; and at a meeting of the Trustees and visitors, it was decided in both Boards to be expedient, that a Professor of agriculture, of botany and of chemistry applied to the arts should be established, and a Professor to enter upon the duties of his office as early in the ensuing spring, as the funds of the institution will allow. For these

funds, the institution is dependant upon public patronage. Nor will they, it is believed, be withheld from the only institution designed to give appropriate instruction to the farmer, the mechanic, the navigator and the merchant, while liberal provision has been always made for educating young men for the learned professions.

Before venturing to commence a plan, which the projectors were sensible was far too great for their means to carry into successful operation, they stated in their petition to the Legislature for an incorporation, what they had been able to do towards the object, but that their exertions alone would be unable to effect it, "and that they must rely upon the patronage of the State for the power of carrying this plan into effect, notwithstanding the exertions they have already made."

The Legislature, the last winter, made to the institution a donation,* which enabled it to continue its existence, and to purchase part of the books and apparatus, which were indispensably requisite. The committee of both houses of the Legislature, who had the subject under consideration, were satisfied, that a much larger sum was requisite to enable the institution to go fairly into operation, and the bill, as passed by the Senate, gave the tax upon the Gardiner bank for three years; but the house, with a caution, becoming in those, who are the constitutional guardians of the public purse, reduced the term, for which the tax was granted from three years to one, so that while the institution might not be deprived of what it could realise in the ensuing year from the grant as passed by the Senate, it would be obliged to apply to the next Legislature, and the grant might then be continued or withheld, as the institution should prove itself worthy or otherwise of the public patronage.

Another instructor having become absolutely necessary, it was deemed by both boards highly important that this additional instructor should be a permanent professor of agriculture, under whose superintendence, the farm which they had always contemplated, might be carried into operation, rather than a temporary assistant. In establishing this professorship in connexion with a farm the Trustees believe, that they shall render an important service to the agriculture of the State. As however, it must be a year or more before the land designed for the farm can be brought into a state fit for agricultural experiments, the Trustees wish to mature their plan fully and have it approved by the visitors, before they lay it before the public. They now give hints of their design, which will be modified as found expedient. The principal objects which the Trustees have in view, in establishing the professorship in connexion with a practical farm are—1st, To give to the future agriculturist the knowledge of those principles of science upon which his future success depends, and to let him see them reduced to practice. 2d, To furnish a beneficial employment as recreation. 3d, To diminish the expenses of the board; and 4th, To try a series of agricultural experiments adapted to the soil and climate of Maine. These experiments will be tried by the students, under the direction of the professor.

* The donation was one thousand dollars from the State Treasury and the tax upon the Gardiner Bank for one year amounting to another thousand dollars.

for, and will be conducted with as much care and accuracy, as the nature of the case will admit.

It would be endless to point out the various experiments which might be pursued upon such a farm, calculated to furnish important results. It is the intention of the Trustees that the labor done by the students should contribute to diminish their expenses. This object will be more easily accomplished whenever they shall be able to have a building on the premises for the students to lodge and board in. The labor on the farm will be altogether voluntary. No student will be obliged to work unless he chooses, but it is presumed that even those, who do not intend to become farmers, will find the labor on the farm a pleasant occupation, independent of every other consideration, and in a moral point of view, the substitution of a pleasing occupation, connected with the highest utility, for the idle sports of their age, cannot but have an important influence on their future character in life.

The Trustees hope to be able to provide some suitable employment for those young men, who may attend the institution with a view of becoming mechanics, by which they may be enabled to discharge their expenses.

Another object of the Trustees is to collect the best models of useful tools and machines. A room will be appropriated to these models, where they will be properly arranged and open to the inspection of the public, and the Trustees take this opportunity of thanking those gentlemen who have already presented them with models of their inventions. The advantages, which would accrue from such an establishment are highly important, but must be obvious.

In conclusion, the Trustees will only add, that, as public good was the sole motive for establishing the Lyceum, so it is the governing principle in all their measures. The whole plan has been arranged with a single reference to the wants of the public, and encouraged as the Trustees have been by the patronage they have already received, by the full approbation of gentlemen, distinguished not only for science but for practical views, and by the interest which is kindling through our widely extended country in the improvement of Agriculture, Manufactures and the Arts, they cannot but hope that the first school, which has been established for the express benefit of the Farmer and the Mechanic, will not be permitted by an enlightened public to languish for want of encouragement and support.

R. H. GARDINER, per order.

Gardiner, Me. Nov. 1823.

Reports of the several Committees of the Worcester Agricultural Society.

REPORT No. III.

Committee on Sheep.

Nathaniel P. Denny, of Leicester, Chairman; James Wilder, of Sterling; Willard Rice, of Spencer.

The Committee on Sheep are happy in being able to state, that the exhibition of fine-woolled Sheep the present year, far exceeds that of any preceding year.

The views of our yeomanry are approximating to the high estimation to which these invaluable animals are entitled. Their utility, however, is not as yet sufficiently appreciated; when this

is done, we may expect to see a handsome revenue collected from the importation of wool, or the agriculturist encouraged to supply our own markets. In either event the benefit redounds to ourselves.

Your Committee are apprehensive that the finest and best woolled Sheep have not been offered for premium, owing to an erroneous idea in the growers of wool, that the appearance of the animal is as important in the view of the judges, as the fineness of the fleece; when the fact is, the finest woolled Sheep are often the most ordinary in appearance, and at the same time are the best entitled to the approbation of good judges. It is hoped a reformation in this particular will soon be effected, and the laudable strife will be who can grow the finest fleece. To this period our manufacturing brethren are looking, with the fond hope that they will be able to vie with the most approved manufactures of the old world.

The exhibition of sheep has been so excellent, the Committee have found it somewhat difficult to decide to whom the premiums should be awarded; but, upon diligent examination and comparison, they have come to the conclusion.

That the premium of \$10 be awarded to Bezael Taft, Jr. Esq. of Uxbridge, for the best Merino Ram; to Joseph Thayer, Esq. of Uxbridge, for the 2d best, \$5; to the Hon. Aaron Tufts, of Dudley, for the four best Merino Ewes, \$10; to the Hon. Salem Town, Jr. for the four next best, \$5; to Bezael Taft, Jr. Esq. of Uxbridge, for the two best Merino Weathers, \$1; to Rejoice Newton, Esq. of Worcester, for the six best Mixed Merino Sheep, \$5; to Asa Rice, of Worcester, for the four best Native Sheep, \$4; to Holland Maynard, of Northborough, for the best Native Ram, \$5.

All which is submitted.

NATHANIEL P. DENNY, per order.

From the American Farmer.

GRASSES.

(Continued from p. 163.)

Long-rooted clover, is a native of Hungary, and I do not think has ever found its way across the Atlantic. The root is biennial, and it sown in the fall, lasts only during the next season. It penetrates to a great depth in the ground, and consequently is but little affected by drought. It, therefore, requires a deep dry soil. The product of this grass, when compared to others that are allied to it in habit and place of growth, proves greatly superior. It affords twice the weight of grass, and more than double the nutritive matter, that is given by the common clover. It gives abundance of seed; and, says, G. Sinclair, "if the ground be kept clean of weeds, it sows itself, vegetates, and grows rapidly, without covering in, or any operation whatever. Four years it has propagated itself in this manner, on the space of ground which it now occupies, and from which this statement of its comparative value is made." This species would, no doubt, prove a valuable acquisition to our husbandry, whether we consider its value for green food, hay, or as a green crop to be turned in preparatory to grain.

Sain Foin is peculiarly adapted to a calcareous or chalky soil. It is true it is cultivated in

Norfolk, Eng. which is a soil of sand and loam, naturally destitute of calcareous matter. But it is common, there, to dress their lands with clay marle, which abounds with carbonate of lime; without which dressing, says Young, Norfolk soils will not grow Sain Foin. This writer considers it "one of the most valuable plants that were ever introduced into the agriculture of Great Britain." The well known Mr. Coke cultivates 400 acres of this grass, and sows it without other seeds. Several attempts have been made to cultivate sain foin in this country, but hitherto, I believe, without success.

Timothy. This grass is distinguished in Great-Britain by the name of *meadow cut-tail*; in New England by that of *herds-grass*. The table shows that it is one of the most valuable grasses that are cultivated.—and, what is worthy the notice of every farmer, that it affords more than double the nutriment when cut in the seed to what it does in the flower. In tenacious, strong and moist soils, it is entitled to a precedence, perhaps, to any single grass for hay; yet, for the reasons does not seem to be suitable for mixing with clover seeds, when intended for meadow. Another consideration which renders it particularly worthy of attention is the seed which it affords, and which may be saved without materially diminishing the hay crop. From ten to thirty bushels of seed, may be taken from an acre of timothy, which at the price it now bears, is of itself, a handsome remuneration.

Fiorin,—has of late years been brought into notice in Great Britain, by the experiments and recommendations of Dr. Richardson; who particularly recommended it for the cold, boggy soils of the mountainous districts, where ordinary grasses would not thrive. The peculiar value of the fiorin, and of other grasses of the *agrostis* family, arise from their fitness for *winter pasture*: as they lose very little of their bulk or nutriment by remaining on the soil after they have ceased to grow. Its name (*creeping bent, or couch grass*) implies a difficulty in mowing it, except on a surface perfectly smooth. We have seen it frequently recommended to the notice of American farmers; but from the very limited progress which seems to have been made in its cultivation, we infer that it has fallen short of public expectation.

Upright bent grass. Dr. Muhlenburgh considers this the *herds-grass* of the southern, and the foul meadow of the eastern states of which *white-top* and *red-top* are varieties. The small weight of hay, and of nutritive matter, afforded by the *agrostis stricta* in the table before us, shows that this grass is more congenial to our climate than to that of England: for, in both quantity and quality, our foul meadow and red-top seem to approach our favorite timothy. In my boggy soils, both varieties of this grass have come in spontaneously, as soon as the ground has been cleared and drained, have soon formed a compact soil, and afforded good hay and good pasture.

American Cocks foot, is wholly unknown to me; and I have not been able to learn much from enquiry as to its merits. M'Mahon calls it the *swamp cock's-foot*; and says it grows well in swamps and moist soils. As it is a native grass, and appears to afford an abundant crop, it is to be hoped that some one acquainted with it will bring it into further notice.

Flat stalked meadow grass. This, according to Muhlenburgh, is the *blue grass* which is considered a pest in many of our tillage grounds. The small crop which it gives, and the little nutritive matter which this affords, shows the little dependence which ought to be placed upon it for grazing or hay.

Reed meadow grass, otherwise *water meadow grass*, is not natural to our country. As it affords a great burthen of hay, and is withal rich in nutriment, it might be a valuable acquisition to our swamp grounds, which constitute its favorite soil.

Smooth stalked meadow grass, is a native plant and is well adapted for permanent pastures. It grows quick after being cropped, and does well upon dry grasses.

Floating Fescue grows well in swamps and bog soils, where good kinds are most wanting. I would suggest, with much deference, whether grasses may not be divided for the *practica* benefit of farmers, into three kinds, to wit:—Cultivated grasses, meadow grasses, and pasture grasses:—and whether these may not be again subdivided to suit different soils and localities. I will illustrate my project, by attempting classification, of the grasses enumerated in the preceding table, from the data which it affords and the practice of judicious farmers:—and

1st. *Cultivated grasses*. All kinds, strictly speaking, which the soil does not produce spontaneously, are cultivated grasses: But the term is generally used, and in the sense I here employ it, applies only to such as are sown to alternate with grain, pulse and roots, in a systematic rotation of crops. The grasses selected for this purpose, are generally the Red-clovers, Lucern, Sain Foin, Orchard, Tall oat, Timothy, or Rye grass. Clover is the primary dependence on all soils which will grow it, and particularly where gypsum can exercise its magical powers. As vegetables are said to exhaust the soil, in proportion to the smallness of their leaves (the larger their leaves, the more nutriment they draw from the atmosphere, and the less from the soil) clovers are entitled to the high commendation they have obtained among American farmers. But as these plants are liable to premature destruction by the frosts of winter, it is both prudent and wise to intermix with their seeds those of some other grass more to be depended on. For this purpose,

On sands, loams, and gravels, and these constitute the soils usually employed in convertible husbandry, the orchard grass, or tall meadow oat grass appear to be best calculated to ensure profit. They grow early, delight in a clover soil, and are fit for the scythe when clover is in the bloom, the time it ought to be cut. The hay from this mixture may be made before harvest commences; and, if the soil is good, a second crop may be cut almost equal to the first. If intended for pasture the second year, either of these grasses will afford more abundant food than timothy.

In cloys, the meadow fox-tail, an excellent grass, might be substituted, though, according to Sinclair the tall oat grass will do well here also. In wet soils, where clovers do not grow well, timothy and meadow reed grass would be good selection, sown either separate or together.

Lucern and sain foin require a deep dry soil, and are generally sown without other seeds. The first does not attain to perfection before

third year; and both, where successfully cultivated, are permitted to occupy the ground in six to eight years.

Meadow grasses. In selecting these, the object is to obtain the greatest burden of good, and to mix those kinds which may be properly cut at the same time.

For clayey and moist soils, many valuable and nutritious kinds seem to be well adapted, that is, say, Meadow Fox-tail, Timothy, Tall oat, Meadow soft grass, floating Fescue, Rye grass, and Meadow, Smooth stalked meadow, American Cock's foot, upright bent or Herds-grass, Tall Fescue. And the five last are peculiarly adapted to swamp or bog soils. For dry loams, sands and gravels, which never ought to be cut long in grass, the cock's foot, or orchard grass, and tall oat, are probably the best; and these might be added, red and white clover. The great difficulty is to prevent the deterioration of meadows. This takes place from better grasses running out, and giving place to poorer kinds, in moss and to useless or noxious plants; aided often by a neglect to keep them well drained. The finer and more nutritious kinds thrive best in moist, though they will live long in wet soils. Hence it is of the importance to keep the surface soil free from standing water, by good and sufficient ditches; and it often becomes necessary, and in most cases advisable on a flat surface, to raise the land in ridges, at right angles with the stream. Another precaution to be observed, is to feed them with stock, when the soil is thin and poachy. Harrowing in the fall, has been found beneficial to meadows. It destroys weeds, and covers the seeds of grasses which have fallen, or may be sown, and thus produces a continued succession of young plants. In Europe, lime is used with good effect as a top dressing to grass lands, as are also ashes. With the annual application of a bushel of gypsum to the acre is found highly beneficial. It only thickens the verdure with clover, but no advantage to most other grasses. Stable manure should be applied only when it can be obtained from the more profitable uses of tillage. As to the means above enumerated fail to insure a good crop of hay, it is time to resort to ploughing and a course of crops.

Pasture grasses. But few of the grasses so valued in Great Britain for pasture, are natural growth of the United States; but it is believed, that if the seeds are once introduced upon our farms, we shall find little difficulty in naturalizing them. Neither the ordinary nor vernal grass, which are said to be indigenous to our country, are recognized in the grass lands which have come within my observation; yet they constitute, with fox-tail and clover grass, the earliest and most valuable varieties for perennial pastures. The meadow clover, and orchard grass, together with our native clover and green meadow grass *poa viridis* (which seldom require to be sown) I think will form the best selection for all grounds which are moderately dry. The rye and oat grasses, or meadow soft grass, might be either sown for the two first, or combined with them. These would afford spring, summer, and fall feed, abundant in quantity, and wholesome and nutritious in quality. On wet soils, where pastures require to be drained as well as meadows, to insure a rich herbage) the Tall

Fescue, Smooth stalked Meadow, Upright bent or Herds-grass may be introduced to advantage. Gypsum is applied to pastures with the same benefit that it is to meadows.

I will conclude this already tedious communication with a request, that you will confer on me a particular favor, by forwarding, if to be obtained in your city, a small parcel of seed of the Meadow Fox-tail, Tall Fescue, Hungry clover, and American Cock's foot, or either of them, the care of Thorburn & Son, New York. I have the Tall oat, Rye grass, Orchard grass, and Lucern growing. Most of the other grasses that I esteem valuable are already among us.

J. BUEL.

NEW ENGLAND FARMER.

SATURDAY, DECEMBER 27, 1823.

We must apologize to our readers for omitting in this paper our summary of foreign and domestic intelligence and a part of our Congressional matter which were superseded by the Report No. ix. of the Massachusetts Agricultural Society.

The communication of "A FARMER" has been received, and we will do all in our power to furnish the information he solicits as soon as possible.

CONGRESSIONAL.

IN SENATE.—Dec. 12. The resolution proposing an amendment of the Constitution to authorize the election of the President, &c. by the people had a second reading. A Memorial from Philadelphia, praying for a revision of the Tariff was committed.

Among the petitions received and referred, was one from the daughter of Gen. St. Clair, stating that the Government is indebted to her late father for military services, and praying for relief, and one from Consul Richard O'Brien, praying for a settlement of his accounts, while at Algiers.

Monday, Dec. 12. Mr. Parrot of N. H. moved that the committee on Naval Affairs be instructed to report on the expediency of authorizing an additional number of Sloops of War to be built and equipped. [Afterwards adopted.]

Mr. Hayne, of S. C. offered a resolution to propose to the State Legislature an amendment of the constitution, so as to provide for the election of President and Vice President by the Electors, and to prevent the election from devolving, in any event, upon the House of Representatives; which was read, passed to a second reading, and ordered to be printed.

Mr. Mason moved that all the resolutions proposing amendments to the Constitution the last and present session, be published in a pamphlet.

The resolution some time since submitted by Mr. Johnson, proposing an inquiry into the expediency of establishing District Courts, and requiring the unanimous opinions of all the Judges, on questions involving the constitutionality of laws, &c. was amended and adopted.

Mr. D'Wolf, of R. I. offered a resolution that the Committee on Commerce and Domestic Manufactures be instructed to inquire into the expediency of allowing a drawback on all articles of domestic manufacture, the raw materials of which are of foreign growth; with leave to report by bill or otherwise. [Adopted.]

House.—Friday, Dec. 12. Mr. Fuller submitted a resolution requesting the President to communicate in the House a plan for a Peace Establishment of the Navy of the United States.

On motion of Mr. Cobb, the Committee of Ways and Means were instructed to report on the expediency of repealing the duty on Salt.

On motion of Mr. Whipple, of N. H. the Military Committee was instructed to inquire into the expediency of amending the Militia law, so as to require that the arms sent to each State and Territory shall be deposited and kept in proper arsenals, ready for delivery to the Militia only when called into the actual service of the United States, or the State or Territorial Government, and to be returned to such place or places of deposit, when said service shall cease.

Mr. Cook submitted a resolution for information respecting the recent robbery of the Land Office at Vandalia, in Illinois, and the justice of releasing the Receiver of Public Monies, from liability to the Government for the sum lost by said robbery.

On motion of Mr. Isaacs it was

Resolved, That the Committee on Military Affairs be instructed to inquire into the expediency of so amending the several laws allowing a bounty to enlisted soldiers or their heirs, and also the laws authorizing the commutation of the land bounty for land pay, may be extended to the children of such soldiers who may have been regularly enlisted, but who may have fallen in action, or died before they were mustered into service, as by law is allowed in other cases.

Errata.—We regret that some errors have occurred in that part of the valuable tract on Grasses by Judge BURN, of Albany, published in our last number. The mistakes existed in the copy from which we took the article, and we hope our readers will take the trouble to correct them with the pen. In the table of Grasses page 161, 1st column 15th line from the top, for "lanatus," please insert *lanatus*. Page 162, 2d column, 8th line from the top, for "I should" insert *sheep*. Next line, for "every" insert *any*. First line in the next paragraph, for "facts are" insert *proof is*. Same line for "in favor of," insert "of the value of."

THE COOKING STOVE.

Did you ever see a cooking stove, Cate?
Why no; but I've heard much about one,
They have grown much in fashion of late,
And some think they can't do without one.

There are others, who think they are dark
And dismal, unsocial and dull:
Of the fire you can see not a spark,
Though it roars full as loud as a bull.

And then while you're a cooking, they say,
Such a fogo beclouds all the room,
That the girls have to group out the way,
In search of the tongs or the broom.

There's the odour and stench of the boiler,
And the smell of the hot burning fat,
And the smoke of the steak on the broiler;
By jingo, I couldn't bear that!

Beside, who could e'er think of eating
A sirloin, a turkey, or goose,
That is baked, like a pumpkin or sweeting,
By the heat of this stinking cambouse?

But, hark ye, now Cate, while I mention,
'Tis prejudice investigates those,
Who deery this most useful invention,
Why, it is just like the tale of the crows.

I tell you, their gabble and prate,
Are nothing but bother and blarney,
If you doubt what I say, my dear Cate,
Enquire of uncle Jo Carny.

He has had one this twelve month or more;
He says there is surely a saving;
He has tried it a hundred times o'er,
And he knows the expense to a shaving.

The labor of cooking is less;
No burning your brains, while you're frying;
No shivering children, half drest,
Crowd under the mantle-tree, crying.

Of wood too, ah, there is the rub!
You save full one third in the burning,
While you're warm as a cat or a cub,
In a chilling and freezing cold morning.

This darkness and gloom is a hum,
I or only just open the door,
You can see all over the room,
To pick up a pin on the floor.

And as for the smoke of the fat,
Of the steak, and the sausage, and tripe;
The fogo and stench, and all that,
Why, it passes all off in a pipe.

The roasting, which some have called baking,
The oven is managed so well,
The difference, if he were partaking,
Epicurus himself could not tell.

Now, Cate, this thing, so derided
By those who know nought of its use,
Its worth would have proved, had they tried it,
Nor suffered so wrongful abuse.

So, here is an end on't, dear honey;
And if you are minded to try one,
I'll step out and saddle our poney,
And ride over to Rich's and buy one.

CHARLEY McCONFORT.

BEAR AND FORBEAR.

Bear and forbear, thus preach the soundest sages,
And in two words include the sense of pages;
With patience *bear* life's certain ills—and, O!
Forbear those pleasures which must end in woe!

MISCELLANY.

ANECDOTES.

An Expeditious Workman.—A Carpenter being at work near the top of a building, stepped on a board not strong enough to bear his whole weight, fell through the floor and broke his leg. A bye stander pretending to comfort him, said, that though he had made a bad job of that business, it must be acknowledged that nobody could go through his work more expeditiously.

Money in the Bank.—A miser having carefully deposited his darling treasure in a bank of earth under a hedge,—in one of his visits to the spot, which contained all his hopes, found his money gone. His lamentations attracted several persons, when a wag, who had more wit than feeling, observed that it "was very surprising that the old gentleman should lose his money, as it was put into the *Bank*."

The Citizen.—A constant frequenter of city feasts having grown very corpulent, it was proposed to write on his back, "*Widened at the expense of the corporation*."

Enquiry on Punning.—A gentleman observed to Mr. Henry Erskine, a great punster, that punning is the lowest sort of wit. "It is so," answered he, "and therefore the foundation of all wit."

A hint to snuff Takers.—A woman asked a Doctor whether taking snuff was not hurtful to the brains? "No," said the Doctor, "for he that has any brains will not take snuff."

ALLITERATION ARTFULLY APPLIED.

Sale of a Steed.—Will be sold on Saturday, at the sign of the Sportsman, near the South Meeting House in Salisbury, at six o'clock, P. M. the celebrated Steed *Swift-Sure*. The following is the sum and substance of the string of superlatives, which shew his superiority.

Swift-Sure is strong, staunch, steady, stout, sound, sate, sinewy, serviceable, strapping, supple, swift, smart, slightly, sprightly, spirited, sturdy, sleek, sure-footed, of sizeable symmetry, shining-sorrel, square-sided, slender-shouldered, sharp-sighted, steps singularly stately—without strain, spasm, spring-halt, stranguary, sciatice, staggers, scouring, surfeit, swellings, scratches, splint, shuffling, or symptoms of any sort of sickness—not stiff mouthed, shabby coated, sinew-shrunk, saddle-galled, short-winded or shoulder-slipped—has neither spleen, sand-crack, staring coat nor shattered hoofs—not shy, skittish, slow, sluggish, nor stupid—he never slips, strays, stalks, starts, stops, shakes, snuffles, snorts, stumbles, and scarcely or seldom sweats—has a showy, stylish, switch tail, and a safe, strong set of shoes on—can feed on saintin, sheaf-oats, straw or spear grass. He was sold six months since for six hundred and sixty six dollars and sixty six cents to Simon Sly-boots, of Salem, who has been offered seven hundred and seventy seven dollars and seventy seven cents in silver for this superb stud-horse.

SIMEON STUMPEMALL.

The Shakers.—Amidst all the singularities of the Shakers, they have some rules which would be well for all denominations to adopt. "It is contrary to order, or the gift, as they call it (says Professor Silliman, in his Tour,) to leave any bars down, or gates open, or leave any thing they use out of its proper place; consequently they seldom have any thing lost. It is according to the gift, or order for all to endeavor to keep all things in order; indolence and carelessness, they say, are directly opposite to the gospel and order of God; cleanliness, in every respect is strongly enforced: it is contrary to order even to spit on the floor. A dirty, careless, slovenly or indolent person, they say cannot travel in the way of God, or be religious. It is contrary to order to talk loud, to shut doors hard, to rap at a door for admittance, or to make a noise in any respect; even when walking the floor, they must be careful not to make a noise with their feet. They go to bed at 9 or 10 o'clock and rise at 4 or 5. Every man and woman must be employed and work steadily and moderately." Trifling as these rules may appear, their adoption would have a very important effect upon any household or community.

Punishment for reading the word of God in the days of popery.—In the parliament held at Leicester, in A. D. 1415, it was enacted, "That whosoever they were that should read the scriptures in the mother tongue, (which was then called Wickliffe's learning) they should forfeit lands, cattle, body, life, and goods, from their heirs forever; and so be condemned heretics to God, enemies to the crown, and most errant traitors to the land." Besides this, it was enacted, "That neither a sanctuary nor privileged ground within the realm should hold them, though they were still permitted to thieves and murderers. And, if in case they would not go over, or were after their pardon relapsed, they should suffer death in two manner of kinds; that is they should first be hanged, and then be burned for heresy against God, and yet neither of both committed."—*Townley's Illustrations of Biblical Literature*.

In England, Mr. Beckford, aged 65, has lately bought the Land-down Farm, to lay it out in a new manner with forest and fruit trees, &c. A man should either in some degree design his work for posterity, or be unconscious of his age. It is pleasant to see an aged farmer planting trees and ordering stone walls—or a venerable citizen building granite and iron. It shews something opposite to selfishness.

Canal Revenue.—Eleven hundred dollars, not long since, were received for tolls upon the Canal, in one day, at Albany.

Knowledge.—Those who know most are most anxious to know more; but those who know but little think they have little need of knowledge.—*Ed. N. E. Farmer*.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but those who pay within sixty days from the time of subscribing will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

NEW ENGLAND FARMER.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

L. II.

BOSTON, SATURDAY, JANUARY 3, 1824.

No. 23.

following valuable communication will be highly
sly appreciated by the good sense of American
rs. It will meet with more attention, and carry
a greater weight of authority from the important
stance that the writer has not given us the *spens*
of theory, but the results of practice. It is a
unvarnished matter fact of relation of what a cul-
has done, the means, expenses, and profits at-
a particular mode of husbandry, and certain ro-
of crops in a light sandy loam.

hope Mr. BUEL will pardon us for printing the
ing article with his name attached, notwithstanding
objections which he stated. An anonymous
will make less impression, and produce less be-
ther things equal, than one which has the signa-
a well known, and respectable author: and we
ken it for granted that Mr. Buel has no insur-
able objection to lending his name to his dis-
al and patriotic efforts to benefit the community.

FOR THE NEW ENGLAND FARMER.

ate of the expense and profits of cultivating
ore of sand loam under two different courses
rops.

Total expense \$93, 65½

PRODUCE.

1st Year, corn, as before 57, 50
2d Year, wheat, do. 35, 75
3d Year, clover, do. 40, 50
400 bushels ruta baga, at
12 1-2 cents 50, 00

4th Year, barley - \$90, 50
5th Year, clover - 23, 75
40, 50

Produce in five years \$248, 00
Deduct expense and rent 93, 85

Profit \$154, 15
or \$30, 82 per annum.

I have omitted to charge for threshing corn
and pitting ruta baga, and to credit for turnip
and ruta baga tops, which may offset against each
other. Two bushels of gypsum should also be
charged, which is sown upon the two clover
crops in the five year course.

It may be well to remark, that potatoes are
embraced with Indian corn, in the first year of
each course; and that so far as the demand will
warrant their culture, they are more profitable,
and less exhausting, than corn.

The above estimates are predicated upon my
own practice for the last five years, and are as
accurate as my memorandums and memory will
enable me to make them, except in regard to
the price of labor, which is perhaps too low,
though it corresponds with average prices.

The propriety of appropriating light loams
and sands to convertible husbandry, that is, to a
succession of grain, grass and root crops, is ap-
parent from several considerations. Such soils
will seldom give more than two good crops of
grass, or grain, in succession, without expensive
manuring or top dressing. Hence they are not
profitable for permanent grass or tillage. But
under good management, and a judicious rota-
tion of crops, they may be made to improve in
quality, and to excel in profit: because they can
be managed with half the expense in labor that
is appropriated to stiff and adhesive soils under
tillage. The history of Norfolk husbandry, af-
fords a demonstration of these truths. Flanders
exhibits a yet more striking evidence of their
correctness. These two districts, which are
mostly composed of smud and light loams, sur-
pass all others in neat and profitable husbandry.
In both, a rotation of crops is the basis of im-
provement. In both, summer fallows are nearly
abolished; and only resorted to to cleanse a
foul soil. In Norfolk, it is a general rule, never
to take two white crops (such as wheat, rye,
barley or oats) in succession*; while the Flem-
ings are equally scrupulous in the observance
of the maxim which enjoins that no field shall
lay more than ten days without a crop.† A late
traveller remarks, that he saw in a large field,
in Flanders grain harvested, and the stubble
ploughed and sown with turnips the same day.

I will subjoin a few observations on each
of the crops embraced in my system of rotation.
And

1. *Indian Corn.* This not only gives more
food to man, and to beast, than any other grain,
but it gives more to the soil, in the form of ma-
nure, where the stalks are fed in a well con-
structed yard, as they ever should be. It is less
exhausting than other grain; first, because of its
broad and expansive system of leaves, which
draw largely upon the atmosphere for food; and
second, because, under my method of culture,
it is cut before the leaves cease to perform this
office, and consequently before the grain de-
pends for its nutriment wholly upon the soil.
It is peculiarly adapted to a loose, warm soil.
Although a profitable crop, on such a soil, when

* Young.

† Radcliff's Flemish Husbandry.

well fed and cleaned, it returns little or no profit from one that is poor, wet or still, I make it the basis of my course. It answers all the purposes of a naked summer fallow, in cleaning the ground, and decomposing the soil. Although clay may require to be summer fallowed, for the further purpose of pulverizing, a fallow crop, and that a hood crop, I believe every reflecting man will admit, answers every beneficial purpose on light loams and sands. I spread my manure, and plough about the first of May. I prefer this time, because the clover has then acquired a good growth,—and, turned under with the manure, affords an excellent bed for the roots of the grain, with ample room to range, and abundance of food to nourish. I then, either with the roller or harrow, close the interstices between the furrows, to prevent the escape of the gasses, and to cover the manure from the exhausting influence of the sun and winds. The decay of the roots soon renders the ground permeable to heat, light, air and moisture, which all contribute to promote vegetation. The seed is then planted in hills, at the distance of 30 inches each way. I pass a harrow, at the first dressing, both ways, and with the hoe do little more than destroy the weeds and grass. At the second and last dressing, I plough shallow, and earth or hill slightly, taking care not to disturb the roots, or to bring the manure to the surface. As soon as the grain is glazed, which has been invariably the first week in September with me, I cut the crop at the surface of the ground, with a hemp hook, laying four hills in a bundle, bind above the ears immediately, take it off the field on sleds, and stook it near my barn—and husk it when convenient. By this course I save labour, double the value of the fodder, and clear my ground in time for wheat. The stooks will not injure if put up wet, the ears keeping the stooks open to the air. The gypsum is sown before the ground is ploughed. All other things alike. I think the clover lay increases the crop from 25 to 30 per cent. and tends to counteract the effects of drought.

2. *Wheat.* The requisites for a wheat crop, are a clear, mellow and rich tilth. If either of these are wanting, or the soil be very porous or sandy, rye should be substituted. If long manure is applied directly to this crop, it introduces weeds and grass; and although the straw may be luxuriant, the grain is often light and shrivelled. If suffered to ferment in the yard, the manure loses nearly half its value in the process. But applied to corn and potatoes in the spring, it enriches these crops by its grosser and more volatile particles, loses its noxious seeds, undergoes fermentation, and becomes by the preparation for the wheat crop, intimately mixed and incorporated with the soil. I harrow down the crowns of the corn hills with a heavy harrow, plough sow and harrow the seed by passing the harrow both ways.

I think you have remarked, that wheat will not grow in old soils which do not contain lime. I do not doubt but calcareous matter is essential in a good wheat soil. In Europe, it is applied to a great extent, in the form of lime, marl and chalk; and I trust we shall soon become familiar with the use of the two former. It cannot be too often mentioned that clay marls generally abound in sand districts, at no great depth, as if to incite the research and industry of man;

and that they constitute the best dressing for the soils which cover them.

3. *Turnips.* These constitute an excellent preparatory crop to barley, as they leave the ground clean and mellow. But how is the crop to be consumed, it will be asked. If near a populous town or village, they will find a ready sale. If not, they may be fed on the ground during all October, November, and part of December, to sheep and cattle. And, lastly, they may be buried in pits, like the Swedish turnip, and fed in the spring, when stock are much in want of succulent food. All I raise are taken to market from the field. The best crops which I have ever seen, were taken upon wheat and rye stubbles. Sandy loams are the best turnip soils.

4. *Barley* grows best on sand loams; and on those is more productive & profitable than oats or rye; rye; and the demand for it is likely to increase with the multiplication of our breweries. It is recommended to roll the crop when three or four inches high. The operation induces the plants to throw up additional shoots, and facilitates the growth of the young grasses.

5. *Clover.* Upon this head I have nothing to say, except to reiterate your recommendation from Anderson, that when made into hay, clover should not be spread from the swath, and but slightly from the cock. It is worth 30 per cent. more, when dried in swath and small cocks, than when spread to an intense sun. If intended to stand more than one year, I sow orchard, tall oat, or timothy grass seed with clover. I prefer the two former on account of their early maturity for the scythe.

6. *Ruta baga.* The value of this plant has lately been subjected to so full a discussion, that I will barely remark, that I have grown it five years, and am confirmed in the utility of its culture.

Without investigating the physiology of plants, it is enough for the present to observe, that they are furnished with different systems of roots, through which the plants are principally supplied with nourishment; that some of these search for food near the surface, and that others penetrate for it deep in the soil; that some render the soil hard and compact—others loose and friable;—that some plants exhaust the soil, while others fertilize it; and that the object of a rotation is, to make such a selection from different classes, as shall produce the greatest profit to the cultivator, without impoverishing his soil. How far the course I have adopted is calculated to attain this end, I leave for the public to determine.

J. BUEL.

FOR THE NEW ENGLAND FARMER.

MR. EDITOR,—If you think the following can in any degree be useful to the public you are at liberty to insert it in your valuable paper.

Manure has become so essential to the growth of vegetation and the raising of good crops that the farmer who has not a quantity of it to apply annually to his land can expect but a small production and consequently, at best, a scanty reward for his labor and toil.

It is, therefore, important that every farmer exert himself to make as much of this valuable article as the immediate benefit and advantages derived therefrom will amply repay him besides essentially improving the quality of his soil and

increasing the value of his farm.—By careful attention and good management every farm may make a sufficient quantity of manure yearly to answer every ordinary purpose in farming. Yet it is an indisputable fact that few make it as much as they might with a little more care and exertion.

It is now ten or twelve years since I have copied a small farm during which time I have paid some attention to the business of making manure.—I have adopted various methods, tried several experiments relative thereto, have hit upon no plan which answers the purpose so well as a careful attention to my hog pen. From them I can obtain a greater quantity of good manure at a trifling expense than in any other way that I have ever tried. I usually keep and fatten four hogs in a year. These keep confined in a yard twenty feet square with a warm and convenient shed attached thereto, a shelter for them during the night time and cold and stormy weather. Into their yard I put the scrapings of ditches, the dirt which continually collecting in and about the dwelling house and other buildings, together with the straw with which they are littered, frequently clearing it out of their house and granting them a fresh supply. During the summer season I often throw in large quantities of weeds, broken and other rubbish that may come to hand, which helps to increase both the quantity and quality of the manure in this way I make from 25 to 30 loads of manure in a year which answers a more valuable purpose than that which I take from the stable or barn-yard.

The last spring I planted a field containing two acres with corn. One half of the piece was manured in the hill with ten loads from the hog pen, the other half with the same quantity of the best manure the barn-yard afforded.

A visible difference was to be seen in the growth of the corn through the season and at the time of harvest the difference was still more discernible. That part manured from the hog pen produced ears generally much larger than that manured from the barn-yard, a great proportion of the stalks bearing two, and many of them three ears each.

Having harvested and measured my corn, I find the result to be as follows:—The produce of the part manured from the hog pen 50 bushels; while that of the other part was but 40 bushels making a difference of 10 bushels in favor of the former.

I have lately taken twenty-eight loads of strong manure from my hog yard which has been collected the past year, and which will be a sufficient quantity to manure two and a half acres in the hill and should the difference be as great it is favor the next, as it has been this year the extra produce will more than repay the whole expense of making the manure.

A FARMER.

Worcester, December, 1823.

'ECONOMY IS WEALTH.'

This laudable remark of Franklin, which has probably seen the means of saving thousands from poverty, is the motto of a sort of family diary, entitled, *The Expense Book, calculated to be a record of Household Expenditures and Common Place Remarks*, published by I. Holt, and for sale by the principal booksellers. It consists of tables in which a square is allotted for

ring in figures the amount of each day's expenditure for nearly all the articles of household consumption and memorandums. Unimportant as such a publication may appear, we consider it of use, and well calculated to promote economy, and impress upon the minds of housekeepers the importance and moral duty of spending less than their income."

The mechanic, (says the preface,) by such cordas as the one here presented, and by economical experiment, may be enabled so to husband his little stock, as not only to live better, but to lay something aside to assist his family in hour of sickness—to bestow upon his children the best of all gifts, education—and to protect those dear ones of his fire-side against the gradation of pecuniary dependence—the insult of the world's pity, and otherwise unguarded coach of misfortune! By knowing the amount of his disbursements, he may ascertain to action how much he ought to save.

Similar considerations addressed to other classes of society. "But after all, it is only to man, with whom originates and abides so large a portion of our happiness, that we must look for that good management which will enlarge the heads of families with their best exertions, to accomplish their laudable desires.—The woman, the guardian of infancy;—the guide, inspirer of youth—the ministering angel of olden age!—it is to woman that man in every stage of existence, is to look for much of his prosperity. But home is the proper sphere of woman: it is her empire. The fireside never so cheerful when the music of her voice is heard—the house is desolate and without a soul when the sound of her light footsteps ceases within it.

It is, therefore, to his fair and amiable countrywomen that the publisher would more particularly address himself, when, adopting the language of Franklin, he says, "economy is wisdom." The discreet wife, be circumstances may, should know the expenses of her family, and her husband's ability to sustain them; that knowledge, how distant may be placed the evil day of want!—with what felicity will the domestic circle meet, which otherwise might sunder for ever.—*N. Y. Statesman.*

From the Portsmouth Journal.

At the request of Mr. William Hall, the patentee of the discovery of curing hake sounds, and manufacturer of the same into Isinglass, we give place to the following articles, from Portsmouth papers, as the subject appears to be interesting, and the discovery may prove a valuable acquisition in domestic economy.

CIDER! CIDER!!

Your casks must be clean, and in every respect well prepared to receive the liquor. In the evening of the day you make your cider, fill it in your cellar. Take one quarter of a pound of Isinglass (made of hake sounds) and put in two quarts of the cider—place it by the fire, and let it simmer and dissolve. Then put it in your hog-head of cider, well secured from the except a small vent hole—and your cider will be perfectly clear, and remain sweet and good for years.—For a barrel, let there be used one ounce.

This Isinglass, or Ichthyocolla, is now made at the Isles of Shoals, from hake sounds, and is the most powerful, as well as the most

pure of all compositions for clarifying liquors, and as a cement. It is prepared by Mr. William Hall, at the Isles of Shoals, and may be had at the shops of the Apothecaries in Portsmouth. The public are greatly indebted to Mr. Hall, the patentee, for this American invention and improvement, upon all that has heretofore been done in Europe.

Mr. Hall's Factory is removed to No. 7 and 8, Ladd-street, Portsmouth.

From the Portsmouth Novator.

I observed in the last Portsmouth Journal a communication relating to the manufactory and use of Isinglass, which I continue to make at the Manufactory No. 7 and 8, Ladd-Street, I feel myself much obliged to the writer of the piece for his politeness in recommending the use of this article for cleaning and purifying cider. The way that I have performed this operation and which has been approved by some of the first characters in the States of Massachusetts, and Maine.—The old casks that have been made use of for this purpose should be filled with water in the months of July and August, in the open air, and be thoroughly soaked out-doors and by the influence of the sun, the casks will become better to put cider in than new casks, braudy pipes, or rum hog-heads just emptied; the God of nature having established his rules far above any that we can invent of ourselves. And with regard to making of cider, it should be made when the wind is from west to north in a clear, free and serene air, grind the apples in the morning, make the cheese and press the same day, take the cider and put into the cellar the same night. Cider made in this way will be as good ten years hence as in the months of April or May, if not better. By the above operation, the color of the cider will be retained, and one quarter of the strength be preserved, that would otherwise be lost by evaporating in the air; the apples that are used to make cider with, should be sound; should there be any rotten apples among them, they should be thrown out; it being much cheaper to throw out half the quantity of apples, should they be rotten, than to grind them with sound ones. The quality of the cider by this operation will be as much better as will pay for the defective apples that are thrown out.

N. B. The way to use Isinglass to clarify cider is to take one quarter of a pound of Isinglass, put it into an earthen picher; and set it by the fire-side; let it simmer; stir it two or three times; and it will be dissolved in one hour; set it away until it is blood warm; then turn it into your hog-head; bung it up; leave the spoil hole open in March or April, and it will be fit to draw off into clean casks or bottles; it is then fit for use, and will keep good for ten years;—hog-heads are preferred; but barrels require a proportionable quantity of Isinglass; when you draw off cider in the months of March or April, you must add one quarter of a pound of Isinglass, that will be sufficient for five or ten years for it to feed upon.

Isinglass is to be sold by the Manufacturer at his Manufactory in Portsmouth.

Pyroligneous Acid.—Knowing the strong prepossessions of the people as to the use of all new articles, it was not supposed that the Pyroligneous acid for the curing of hams, and other

species of animal flesh, would go into general use the first year; but notwithstanding all prejudices, several barrels were retailed to the citizens of Utica and its vicinity the last year; the result of which experiment was demonstrated beyond contradiction, that the smoking of hams and other kinds of meat in this way is altogether to be preferred. Some of the most respectable gentlemen of this town have given it their decided approbation in several particulars. First, the hams are not exposed to any change or decomposition near the bone, as they many times suffer when the heat is carried too high while hanging in the smoke house; secondly, the hams may continue in pickle through the warm season without any particular attention, from which they may be cooked at any time, containing all those excellent qualities peculiar to that dish. The idea of hams drying has unquestionably arisen from necessity and not from any supposed improvement. Thirdly, no trouble is necessary, except to put one quart of acid in two hundred pounds of hams after they are sufficiently penetrated by the salt.—*Utica Gazette.*

CANALS.

Mr. Jonas P. Fairlamb, of this borough, has discovered an important improvement for saving and re-applying water to canal locks, for which he has obtained Letters Patent from the United States.

This improvement we understand to be as follows: the application of a horizontal side of a Lock, with valves communicating with the different chambers of the cistern, in the side of the Lock, and corresponding with those chambers—those valves are so constructed as to throw open at once a space to each chamber of the cistern in succession, of from 60 to 70 square feet, according to the length of the Lock, opening and shutting in succession from top to bottom when emptying, and from bottom to top when filling the Lock. By this improvement the Lock will be emptied and filled much sooner than locks upon the common construction, in consequence of the large spaces thrown open for the water to pass from, and return to the Lock, and with perfect safety. In no case will those valves bear to be opened with a greater head of water than two chambers when emptying, and one when filling the Lock. Those chambers may be so constructed as to save and re-apply almost any given quantity of the water usually lost. This cistern is on an entirely different construction from the side Locks and side ponds in use in Europe.

Preparation for Cleaning Plate.—Take four balls of the finest whiting, crumble it to a fine powder, the finer the better; two pennyworth each of spirits of wine and camphor, spirits of hartshorn and spirits of turpentine, half an ounce of quicksilver, and a penny-worth of rose pink; put the quicksilver into a phial, with about half the turpentine, and shake it till the quicksilver be killed, then mix all the ingredients together, and the whole is fit for use (The quicksilver and a little turpentine should be first beat up with a skewer or fork, in a large cup, till it becomes thick as a salve.) After it is thus made, it should be suffered to grow dry, a little of it being wetted with water when used. The mixture is to be rubbed on the plate with soft leather, which becomes better for use.

Facts and Observations relating to Agriculture and Domestic Economy.

[BY THE EDITOR.]

ON THE USE OF SALT AS A MANURE.

[Continued from page 170.]

The following passages relating to this subject are extracted from the "Letters of Agricola," by Mr. Young, of Nova Scotia, a work to which we have often been indebted, and frequently recommended to the attention of our readers.

"In the report of Cheshire drawn up for the Board of Agriculture, the writer has meritoriously fixed his attention on the supposed effects arising from salt, because it is more abundant in this than in all the other counties in England, and has registered some circumstances bearing on the same conclusion that is derivable from our experience. He has selected two facts which would seem to establish that this substance, though applied in moderate quantity, is invariably attended at first with the destruction of vegetable life; but after the greater part of it has been dissolved by the rains and has sunk in the soil, the remainder imparts a new energy to the roots of those grasses which it had previously well nigh killed. Time and the operation of the common elements of air and water thus change its character and modify its effects. After draining, he says, some sourish land in October, refuse salt was spread on one part at the rate of eight, and on another of sixteen bushels per acre. In a short time, all vegetation vanished, and next April not a blade of grass was visible. But towards the end of May a rich verdure sprang up after the eight bushels, and in July a still richer after the sixteen; and to this day, though ten or twelve years have intervened, a superior luxuriance is the effect. Again he mentions that a small quantity of fossil salt, was laid on a court pavement to destroy the vegetation. Not a blade was to be seen the first year; but in the second, the grasses started up more vigorously than ever.

"Though this barrenness grows out of an undue impregnation of the soil, it follows not, that salt is deleterious in minute quantities.—In accordance with this view of the matter, refuse salt by the Cheshire farmers is esteemed an excellent manure, either for pasture or fallows; but it should, they affirm, be first raised and incorporated with earth, roots, weeds, and other substances."

"In Aiton's report of the county of Ayr there is brought forward a collateral confirmation of the utility of salt on land. Sea water is taken and evaporated till the salt contained in it can be merely kept in solution. With this strong brine, lime-shells, [lime fresh from the kiln] are slaked, and mixed to the consistence of soap's waste. This quantity is either spread singly on an acre, or made into a compost with forty cart loads of peat earth; and this last method is accounted the preferable of the two. This new species of manure has stood the test of comparison with other kinds, and in no instance has it fallen short of the most ardent expectations. It has been found peculiarly favorable to the growth of wheat and beans; and all corn crops as well as the grasses which succeed have been benefited by it.

"But the testimonies in favor of this saline

body are not yet exhausted. In Cornwall the refuse salt of the fisheries is anxiously looked after by the neighboring farmers, and has never failed to produce the most wonderful effects. This may be partially traced to the oil and entrails of the fish incorporated with it, which afford animal matter for decomposition; but only partially, for it is beyond all doubt from the nature and abundance of the evidence that they are referable in part to the action of the salt.

"At the brine pits of Droitwich, Worcestershire, where pan salt is manufactured, the refuse was there also sought for by the farmers, who preferred it to all other manures, though charged with the agricultural duty: so that it is clear, from so many concurring suffrages in its behalf, that it has acted beneficially in these places.

"There may be more difficulty in developing its mode of operation. That it is offensive to grubs and other vermin which prey upon crops has, I believe, been fully proved; but it is more probable that its principal usefulness is dependent on its forming a component part of the organization, as do lime, plaster, and the alkalis. It is a substance very generally diffused throughout nature, exists in most soils, and is a frequent accompaniment of the animal and vegetable manures. In the usual processes of vegetation it must, therefore, be present, and it is only required by plants in very minute portions."

In a treatise on fruit trees, by Thos. Hitt, London, the following passage occurs.

"To show an acquaintance of mine the effects and advantages of salt properly applied to vegetables. I made the following experiment in an extreme dry summer; upon a bare piece of pasture land, out of which the cattle were taken for want of grass; I marked four places with stakes, each of which I watered nine nights successively, in the following manner:—the first with spring water alone, to the quantity of a gallon; the second with the same quantity of water, adding an ounce of common salt; the third and fourth with the same quantity, mixing the water in the third place with two ounces of salt; and that in the fourth with three ounces, which produced the following different effects.

"The grass in the second place grew more and of a darker green than that in the first; in the third it only grew by spots for part of it was killed where the greatest quantity of water fell, and the fourth was quite brown for a greater compass than the third; by which it appeared that an ounce of salt to a gallon of water had a better effect than the water had alone; and that three ounces of salt, mixed with a gallon of water was more than the grass could immediately receive; but the fourth place in the spring was the most fertile of them all."

L. R. Legrand, Esq. whose Observations on Manure are recommended as being very valuable in Young's Annals of Agriculture, vol. v. page 149, recommends "sixteen bushels to be a proper quantity for one acre," a fact which he says he ascertained by repeated experiment. Forty bushels to the acre, he says, will destroy vegetation.

A pamphlet was published in England, entitled, "Hints to country Gentlemen and Farmers, on the importance of using salt as a general ma-

nure. By the late J. Holinshead, Esq. of Croydon. Third Edition, 1802."

This writer says in substance, that common salt is the most powerful manure in nature, it insures a certain destruction to weeds and insects—that it gives luxuriance and salubrity to grass lands, and adds, "When a farmer tends to follow a piece of ground, he must first sow it with such a quantity of salt would be sufficient to destroy all vegetation, forty bushels per acre; which by cutting and dividing the vicious substances which are on the earth, would reduce it into a proper soil to become food for plants. The farmer must take notice that this salt is to be sown on the ground sometime before he begins to work with the plough, (the autumn will be the most proper season) in order to give the soil sufficient time to destroy the grass and other roots upon it, before he begins to work it. The salt being thoroughly mixed and incorporated with the soil, during the winter and summer following, whilst the land is on the plough will by the time the seed is sown upon it, be reduced to that strength which is most proper for effectually and vigorously assisting and supporting vegetation while the seed is in the ground, and such lands will be found to produce a crop superior to those under any other mode of cultivation. (TO BE CONTINUED.)

* For copious extracts from this Pamphlet, see *American Farmer*, vol. v. page 269, and sequel.

† The quantity refers to *fool* salt. Of pure salt the quantity would meet the views of the writer.

Reports of the several Committees of the Worcester Agricultural Society.

REPORT No. IV. Committee on Swine.

Lovett Peters, of Westborough, Chairman; Jos. Hinds, of West-Boylston; Silas Brooks, of Worcester.

The Committee on Swine, having attended to the duties of their appointment, respectfully Report,—

That there were in the pens 48 Swine, excellent appearance, and some of the best nearly equal in quality, that the Committee found it very difficult to determine which were entitled to the premiums; but finally award follows, viz.

To Samuel Harrington, for the best Boar months old, the premium of \$10; to Jonathan Knight, for the best breeding Sow, 18 months old, the premium of \$6; to Messrs. Ward & Rice for the best weaned Pigs, 6 months old, the premium of \$1.

The Committee particularly noticed the Sow and Boar and 4 pigs of Mr. Silas Dudley—the Sow and Pigs of Mr. Isaac Temple—the Sow and Pigs of Mr. Asa Rice—the Sow of Messrs. Ward & Rice—the Sow and pigs of Col. Her Penman—the Sow and Boar of Hon. Oliver Fiske.

The pigs of Mr. Jacob Hinds, though small in size, are good shaped.

The 15 pigs of Mr. Stephen Salisbury, for their goodness of shape and equality of size are a very extraordinary lot of Pigs for such number.

If any of the Swine which were in the pens are not noticed, it is by mistake, not by design. Considering the very fine exhibition of Swine

Committee regret that they were not advised to award premiums to more of the designs, all of which is respectfully submitted. By order of the Committee.
LOVETT PETERS, *Chairman.*

REPORT No. V.

Committee on all Articles manufactured of Cotton, Wool, Flax, and silk.

Leel Taft, jr., of Uxbridge, *Chairman*; George Hall, of Mendon; John Lees, of West-Boylston; David Poignard, of Lancaster; Lemuel Davis, of Holden.

The Committee appointed to examine all articles manufactured of Cotton, Wool, Flax, and silk, and award premiums to the most deserving, with great care attended to the duties of their appointment, and submit the following Report.

Our Committee met at the room appropriated for the exhibition of manufactured articles, immediately after the expiration of the time allowed by the rules of the Society for competitors to make their necessary entries. The articles exhibited to their notice, with a view to premiums, were uncommonly numerous, and generally of superior excellence to those exhibited on former occasions. Many other specimens of ingenuity and success in the useful arts of manufacturing industry, were offered, especially with a view of giving an increased interest to the occasion.

To those who have gratuitously tendered aid in promoting the objects of the institution we cheerfully offer the thanks of the Society. The tendency of such zeal is to excite emulation in the laudable pursuits of life, diffusing knowledge of what may be effected by industry skillfully applied, and promote, in a high degree the best interest of the community.

The consideration is peculiarly gratifying to see the rich display of articles to which our attention has been at this time directed, has not been from the novelty of the occasion. Our anticipations have been again and again repeatedly increased interest. The progress of the Society has been marked by an unequivocal movement in all the important interests of the country. The community is at length convinced of the utility of the institution; and at the aid of novelty, we trust, every such anniversary will excite a more lively interest, from an increased variety and the improved quality of manufactured articles offered for public notice and competition.

The Committee regret that the very limited number of premiums offered for Domestic Manufactures prevented their awarding them, in instances, for articles of uncommon excellence. But a single premium was offered for the article of Broadcloth, and but one for Flannel. It will, however, readily occur to every gentleman concerned in that useful element, that with them the consideration of a premium can afford no inducement to object of competition with them is to establish the reputation of their fabrics and promote the objects of the Society. These objects are completely answered by the preference given to the most successful competitor, in the exhibition of your Committee.

Being indulged in these general remarks,

justified we trust by the circumstance of the occasion, your Committee will now report the premiums they have awarded.

To Messrs. Slater & Howard, of Oxford, for the best superfine Broadcloth, the premium of \$15.

Next to the specimen offered by Messrs. Slater & Howard, your Committee gave the preference to a deep blue cloth offered by Mr. Thomas Bottomly, of Leicester, probably in no respect inferior to the best specimen offered on any former occasion.

The Wolcott Manufacturing Company, of Southbridge, presented an elegant black cloth, excelling in the delicacy and uniformity of its thread, and extremely well manufactured in other respects, but, in the estimation of your Committee, wanting in an important particular, a stout body.

To the Wolcott Manufacturing Company for the best Cassimere, the premium of \$10.

That establishment has long held the palm for the manufacture of that article; but we assure them that their claim was closely contested on the present occasion, by J. Adams & Co. of Douglas.

The cloth offered by Messrs. Adams & Co. was perhaps equally delicate, but promised less durability.

Mr. George Wall, of Mendon, presented, merely for exhibition, a piece of Cassimere, extremely well manufactured, but of more ordinary stock.

Mr. James Southwick, of Medway, presented two pieces for exhibition that did him much credit as a manufacturer; but not being a citizen of the County, could not be a competitor for premium.

Mr. James Mann, of Medway, offered to our notice a superior specimen of Sewing Cotton, manufactured at the Union Factory in that town. The article is highly important in the domestic economy of every family, and we hope the spirit that has induced an exhibition of the article on the present occasion, will insure every improvement in its manufacture of which it is susceptible.

To Miss Hannah Blair, of Worcester, for the best Carpeting, the first premium, of \$15.

To Mr. John Hunter, of New-Braintree the second premium, of \$10.

To others presented by Miss Polly Whitney, of Worcester, and Mrs. Mary Adams, of Grafton, deserve particular notice. The ones presented by Miss Whitney and Mr. Hunter, divided the suffrages of your Committee, but in the opinion of a majority, the brilliancy of color, and their tasteful arrangement, gave to Mr. Hunter's the preference.

Several others were offered, of substantial fabric, and but little deficient in other respects and we hope the competition on the present occasion will tend to render this useful article fashionable in every respectable family.

To Samuel Dadman, of Templeton, for the best Woollen Cloth, of household manufacture, the 1st premium, of \$8; to Lovett Peters, of Westborough, the 2d premium of \$5; to Levi Sawyer, of Bolton, the 3d premium, of \$3; to Jonathan Wilder, of Lancaster, for the best Flannel, 7-3 wide, the 1st premium, of \$10; to Jerome Gardner, of Harvard, the 2d premium of \$5.

Mrs. Nancy Haquember, of Worcester, pre-

sented a specimen but little if at all inferior to that offered by Mr. Gardner—your Committee must give a preference, and of the two, Mr. Gardner seemed to deserve it.—He therefore obtained the pecuniary reward; but the credit must be nearly equally divided between them.

Miss Clarissa Fay, and Mr. Conyers, both of New-Braintree, presented two other pieces well manufactured, and of good stock; but rather too stout for the common purpose of Flannel.

To Miss Betsey Delano, of New-Braintree, for the best Linen Sheetting the premium of \$8, to Miss Priscilla Putnam, of Grafton, for the best Linen Shirting, \$3.

Several other specimens of Linen Sheettings and Shirtings, presented by Miss Hannah Holmes, of New-Braintree, Mr. John Temple, of West-Boylston, Mrs. Anna R. Putnam, of Grafton, and Mrs. Abigail Stone, of Ward, claimed the particular attention of your Committee, and are entitled to high commendation.

To Jonathan Moore, of Holden, for the best Woollen Coverlet, the premium of \$4.

Your Committee cannot but notice two others presented by Thomas Chamberlain, of Worcester, and Zebulon Carey, of Ward—the former of very firm fabric, and the latter uncommonly elegant.

To Miss Patty Leland, of Grafton, for the best Linen Table Diaper, 5-4 wide, a premium of \$8; to Miss Polly Leland, of Grafton, the 2d premium, of \$5.

A specimen presented by Levi Goodale, of West-Boylston, was decidedly superior in its fabric to the one of Miss Polly Leland; but wanting in the number of yards necessary to obtain a premium.

The Committee regret that several of the pieces offered to their notice were materially injured in bleaching. Those who manufacture Linen, and do not bleach it in the ordinary mode of field bleaching, ought to be cautious to whom they entrust it for that object. Many persons skilled in bleaching Cotton, know little of the operation of chemical preparation when applied to Linen.

To Mrs. Hannah Edson, for the best Half Stockings for Gentlemen's wear, \$2.

Several other specimens of Gentlemen's and Ladies' Hose were presented by Mrs. Sarah Gale, of Westborough, Mrs. Robinson, of Worcester, Jonathan Davis, jr. of Oxford, Seriah Hunter, of New-Braintree, and Mrs. Hannah Sawyer, of Bolton, surpassing any thing of the kind of household manufacture ever witnessed by your Committee.

To Mr. Lemuel Healey of Dudley, the sole claimant for a premium on Sewing Silk, the sole premium of \$5.

Your Committee cannot but regret that the manufacture of Silk excites so little attention in this Commonwealth. The article has for many years been manufactured in Connecticut with great success. It requires but a little land to produce Silk to a very considerable amount; the labor can be performed by children and females, and would certainly be a very profitable employment in many families in the County.

Your Committee will close its Report, necessarily lengthy, by noticing two Counterpanes presented by Miss Polly Underwood, of Northborough, and Miss Rhoda Ayers, of New Braintree. Also, a specimen of Linen Sewing Thread,

by Jabez Brigham, of Worcester. Had premiums been offered for these articles, they would have been cheerfully awarded.

In awarding the foregoing premiums, your Committee have unquestionably disappointed many, and probably done injustice to some; but when competitors consider the extra difficulty of balancing the claims in many instances, we hope disappointment in the present instance will not prevent future competitors.

Per order,

BEZALEEL TAFT, jr. *Chairman.*

From the Old Colony Memorial.
AGRICULTURAL.

As one who feels a deep interest in the success of our Agriculture, I cannot but regret the ill success which has attended the experiments of "Plymotheus" in attempting to investigate "the natural history; the habitudes of life; the character, the change, the metamorphosis," &c. of the Grub-Worm, whose devastations for several years past, have excited the attention of farmers in this section of the country. With due deference however to the opinions of Plymotheus, I cannot agree with him in supposing, "that the devastation of the three or four last years may be intimately connected with the character of the seasons, which being peculiarly arid, may have driven them to the necessity of seeking moisture from the vegetable creation, to preserve their existence," if by this statement he means to infer the probability, that their devastation will accompany every dry season, or that, if the present season had been similar to the last, similar injury would have been sustained from the worms.

The summer of 1831 was not so arid by considerable as that of 1823; yet in this vicinity the devastation by the worms in the former was very great, while in the latter there was not, so far as my observation extended, any injury done by them. My opportunity to observe was not very limited; in other towns I observed their devastations, particularly in Plymouth; but in this town I saw none; though, in the year previous, the grass, in many places, was wholly destroyed; the corn was much injured; and early sown winter grain was spoiled. The year 1815 was not, if my recollection is good, a very dry season; yet from about three fourths of an acre of good land well tilled, I harvested only four bushels of corn in consequence of the ravages of the worms. Much of the corn did not ear at all, and some of it never reached a foot from the ground. Winter rye sown on the same land, was nearly all destroyed in the latter part of the season, and most of the piece was not worth harvesting. Grass was much injured, and potatoes were nearly spoiled. The same damage was evident on many other farms in this vicinity. During the succeeding year, 1816, no injury was done to those farms which suffered the year before, though the worms were frequently seen near the surface of the land; yet this was not remarkable for being a wet season.

From these facts I am led to the conclusion, that the worms do not commit their ravages, except at fixed times, even though the season should be arid; otherwise, why were not the fields of Middleborough ravaged in 1822, which was remarkable for drought. I would not be understood by this, to maintain that the peculiarity of the season has no effect upon the

worms: I admit that a dry season may increase their ravages, or a wet one prevent them, should they happen on those years in which the worm is in its period for committing its devastations.

Middleborough, Sept. 9, 1823.

Domestic Manufactures.—The Steubenville (Ohio) Factory, established for the purpose of manufacturing woollen goods, has recently commenced the manufacture of carpeting, and it is said that the fabrics produced are as handsome as the Scotch or Venetian, and superior to the English carpeting.

NEW ENGLAND FARMER.

SATURDAY, JANUARY 3, 1824.

GARDINER LYCEUM. In our last, page 172, we published the "Address of the Trustees of the Gardiner Lyceum," but were compelled from want of room, to omit some observations, which we intended should have accompanied the publication of that Address.

The plan is novel in the United States, altho' institutions in some degree similar, have been for some time established in Switzerland, and some other parts of Europe. The course of education, pursued at our colleges can be of little use to those whose pursuits in life are destined to be agricultural, or mercantile, or to those who propose to devote themselves to the useful or ornamental arts; or indeed to any not intended for what are styled the *learned professions*. But, let a man's pursuits be what they may, "knowledge is power." Still that kind of knowledge which has the greatest affinity to a person's vocation will generally prove most useful, and give him the most power.

It is understood that the expenses of an education at the Gardiner Lyceum are moderate; which will give an opportunity to many to pluck the golden fruits of science, who could not otherwise attain them. The course pursued, by combining *practise with theory*, must be of inestimable advantage to a person whose object is to make his knowledge useful to himself or to the community. We wish the institution may be as successful as it promises to be beneficial, and that the dews and sunshine of public patronage may prevent a bud from withering, which promises fruit of great value to the community.

CAUSE OF THE GREEKS. A general sympathy with the distresses of the Greeks, and a disposition to aid them in their arduous struggle appears to pervade the U. S. and is highly honorable to our citizens. If the war in which the descendants of Epaminondas, and Leonidas are engaged was of a common character, their claims would be less imperious. But with the Greeks there should seem to be no alternative between *death and victory*. They must conquer or the adult males will be exterminated, and the women and children reduced to a slavery of the most horrible description. The apathy with which the Great Powers in Europe remain spectators of this struggle is disgraceful to them, and a stigma on human nature. Should the Emperor Alexander alone, merely raise his voice, he might secure freedom to the Greeks, even without lifting his hand. But the cause of the Greeks, is connected with that of *Liberty*, and absolute monarchs attach ideas to that sound which cause them to tremble, and their thrones to totter. But surely a free people ought to assist a people determined to be free; and it is hoped that no petty calculations relative to the saving of cents will close the hands, or harden the hearts of a liberal and high-minded community. Besides, if we consulted our interest alone we

should render the Greeks all the assistance in our power. If they fall or their chains are again riveted, the alliance of absolute power will be strengthened, and the United States will be exposed to contend single handed with a *Coalition* which appears to be determined that Freedom shall not exist and a Republic Government be known only in theory, and the records of abortive attempts to improve the condition of the human race.

The committee of the Greek Fund, have acknowledged the following donations:

J. B. Yates, Esq.	-	-	\$100
H. Rutgers, Esq.	-	-	100
G. C. Verplanck,	-	-	30
Soph. Class, Columbia College,	-	-	64

Union Academy Hall,	-	-	50

In the London papers the Society of Friends said to have raised and expended a larger sum for succour of the Greeks in their present struggle, than has been furnished by all the other denominations Christians together, in the British dominions.

Composition for rendering Boots and Shoes impervious by Water.—Take one pint of boiled linseed oil; a pound mutton suet; six ounces of beeswax; four ounces of rosin; melted, mixed, and stirred while cool.

FOREIGN.

Fate of Riego.—The Spanish Chieftain, Riego, been condemned to death, and executed at Mac. The following is a copy of his sentence.

"D. Rafael del Riego is condemned to the ordinary punishment of hanging, and he shall be drawn a hurdle to the place of execution—his property shall be confiscated and he shall pay the costs of suit."

Independence of South America.—The London Courier of November 10, contains an article of some length on the subject of Great Britain's acknowledging independence of the South American States, which concludes as follows:—

"We have sent Consuls and Commissioners, and powers may and probably will do the same. We thus a *de facto* acknowledgment of the Sovereignty of the American States—and we may expect further a higher diplomatic character will either be sent or that some one of the Commissioners has or will the power of taking upon himself that character soon as the different consuls have made their report upon the situation and feelings of the states to which they have been respectively sent."

Spanish Affairs.—A London article of Nov. 10, says that the capitulation of Barcelona was signed by Mina on the 11th November and the French took possession on the 4th. Lerida was occupied by the French on the 8th Nov. The garrison (5000) to be prisoners war. Badajoz capitulated on the 29th Oct. All Constitutional Chiefs have submitted to the excess of the Empecinado, and he is actively pursued.

From Spain latest.—Capt. Winsor has arrived Malaga, which place he left on the 15th ult. He says that Ceuta had been taken possession of by the French who had openly declared they would never give so long as the English held possession of Gibraltar and that on the 13th of Nov. news was received Malaga of the surrender of the cities of Alicante, Cartagena and Barcelona to the French and Spanish Authorities.—*Boston Continued.*

Tunnel under the Thames.—A plan has been

England for making a tunnel or passage under Thames at Rotherhithe, where the river is navigable of the largest borthen. The distance is 1140 feet. This was attempted in 1809, and excavation was carried 1011 feet, and within 30 of the opposite shore, when a body of quick sand way, and filled the passage. The plan lately used is to remove no more earth than is to be used by the body of the tunnel, retaining thereby the undraining ground in its natural state of density and dry. The excavation is to be 34 feet in breadth 3 feet six inches in height. A more copious description of this plan, together with an explanatory cut can be seen in the American Farmer for Dec. 19, vol. 5, p. 305.

Paris, during the year 1821, 42 persons died by vapour of charcoal in confined apartments.

India Congress.—A Barbadoes article of Dec. 1821, that a recommendation has been made for a meeting of Delegates from all the Colonies for the purpose of making an appeal to Parliament on the subject of the existing situation of the W.I. Colonies.

Apparances.—Orders were sent on the 10th, to Portsmouth for two 30 gun ships supposed to be intended for the South American service. One of the ships was on board one of these ships and a 71, for foreign service.

DOMESTIC.

Spectator, published at Edwardsville (Illinois,) that twenty miles to the eastward of Carlisle, in that State, there is a well, of the water of which is salt, equal in quality and effect to that of Epsom land. The well is capable of affording daily hundred gallons of water, which being evaporated, yield at least fifty pounds of pure salt.

Accident.—A most distressing accident occurred in London on Saturday last. Mr. Moses Preston, an importable farmer of Danvers was thrown from the top of his wagon, while the horse, having been running at full speed; the wagon came in contact with a post, he had both his thighs broken, and he otherwise severely injured by the shock. Mr. Preston has exhibited a remarkable firmness in this accident, yet his recovery is not considered probable. Mr. Preston's right thigh is broken in two places, his left thigh broken once, and his left leg broken literally broken to pieces.—*Salem Gaz.*

Accident.—In raising a saw mill in China, Me. on the 15th Dec. the frame being partly raised, gave way, by which a Mr. Hamilton, of Palermo, was severely wounded. He died a few days after, leaving a wife and ten children to lament his loss. Several others were severely injured.

Death of Capt. Tayer, of Portsmouth, there was recently picked from one of the trees, after the second growth of the last season.—*R. I. Am.*

CONGRESSIONAL.

Monday, Dec. 15. The Speaker laid before the House a list of the balances on the books of receipts and expenditures of the Register of the Treasury, which appear to have been due more than two years prior to Sept. 30, 1823.

A resolution was moved by Mr. Fuller, and adopted, that the President of the United States be requested to communicate to the House a plan for the establishment of the Navy of the United States.

On motion of Mr. Poinsett, of S. C. the Committee on Affairs was instructed to inquire into the expediency of authorizing the construction of ten additional ships of war.

Further moved, that the Naval Committee be instructed to inquire into the expediency of associating the Military Academy at West Point, a School of Instruction for the Midshipmen of the Navy of the U. S. Also, on the expediency of securing in the Department of the Navy, the benefits of professional skill and experience, by a due appointment of the surgeons and their mates, and by re-

quiring an examination by a Board of Physicians, of all persons applying for admission therein.

The Committee on Commerce was instructed to report on the expediency of imposing a duty on wheat, imported from any foreign ports.

Tuesday, Dec. 16. Mr. Webster from the Judiciary Committee made a report against the propriety of giving concurrent jurisdiction to the State Supreme Courts in certain cases under the Patent Law. Laid on the Table.

Mr. Kent, of Md. offered a resolution for the appointment of a Committee to report on the expediency of making such an appropriation of lands in those States to which no grants have yet been made as will correspond in a just proportion with the appropriations which may have heretofore been made in favor of other States.

In SENATE.—Thursday, Dec. 18. The bill to appropriate \$35,190 for the relief of Daniel D. Tompkins, passed by general consent.

Mr. Lloyd, of Md. proposed a resolution that the Committee on Naval Affairs be instructed to inquire into the expediency of regulating or prohibiting, by law, the transportation of gold, silver and jewels in the armed vessels of the United States. [Adopted next day with an amendment proposed by Mr. Lloyd, of Mass. to inquire into the propriety of permitting public vessels to carry passengers.]

Monday, Dec. 22. Mr. Smith, of Md. submitted a resolution directing the Secretary of the Treasury to furnish a statement shewing the exact amount which will be due and payable to the Commissioners of the Sinking Fund. [Next day agreed to.]

The other business transacted by the Senate down to the 25th was either of a private or local nature.

House.—Wednesday, Dec. 17. On motion of Mr. Strong, of N. Y. the Naval Committee was instructed to report on the expediency of selling the schooners and vessels purchased under the act for the suppression of piracy.

Thursday, Dec. 18. Mr. Williams, of N. C. submitted a resolution that the President of the U. States be requested to lay before this House any information he may have received, and which he may not deem it improper to communicate, relating to the present condition and future prospects of the Greeks.

On motion of Mr. Trimble it was resolved that the Committee on Military Affairs be directed to inquire into the expediency of authorizing the President of the United States to direct sales to be made, from time to time, of such arms, ammunition, and military stores, as are not wanted, or are unfit for public service.

Friday, Dec. 19. Mr. Webster gave notice that he should move for the consideration on Monday, fortnight, of the resolution he submitted some days ago, proposing to send a mission to Greece. Some other business principally of a private and local nature, was discussed, and acted on.

Monday, Dec. 22. Mr. McDuffie from a Committee on the subject, reported several joint resolutions for amending the Constitution of the United States as it respects the election of President and Vice President; which were twice read and committed.

Mr. Livingston submitted resolutions relative to the erection of light houses at different points on the Coast of Florida.

Mr. Breck offered a resolution that the Secretary of the Treasury be directed to furnish information respecting the commercial intercourse between the U. States and the Turkish and Grecian dominions.

Tuesday, Dec. 24. Mr. Mallary's resolution was agreed to without opposition.

On motion of Mr. Tucker, the old Beaumarchais claim was referred to a select committee.

On motion of Mr. Buck the Committee on Military Affairs was directed to enquire into the expediency of authorizing the Secretary of War to permit the issue of ammunition to Capt. Alden Partridge for the use of the pupils of his Academy.

A bill to continue for five years longer, the Half-Pay pensions to the children of officers and seamen, &c. of the Navy who have died in the service, after some debate was ordered to a third reading.

Erratum.—In our last paper, page 176, 18th line from the top of the 3d column for "and" read to. Next line insert a comma after the words "Gen. Hull."

A New and Valuable improved Implement.

JUST completed and for sale at the AGRICULTURAL ESTABLISHMENT, No. 20, Merchants' Row, Boston, an improved Straw Cutting Machine, which from its plain and simple construction is very effective in its operation, and is a great improvement on the various machines invented for this purpose; the power being applied in such a manner as to greatly increase the operation of the machine and places the workman in so convenient a position, as to enable him to tend and work with perfect ease and convenience to himself and so timed as to cut any length of fodder required. Dec. 20.

FARMER'S ALMANAC, FOR 1824.
FOR sale at this Office, the Farmer's Almanac for 1824. Nov. 24.

NEW YEAR'S ADDRESS OF THE NEW ENGLAND FARMER'S BOY TO HIS PATRONS.

Good people all, of every station,
Who constitute our mighty nation,
Permit a humble Farmer's Boy
To wish your Worship to enjoy,
Through this, and many a merry year,
Health, happiness and Farmer's cheer.—
Prime pork and beef, nice pumpkin pie,
And cider-bark never dry—
A good roast turkey for Thanksgiving,
Which make what I should call good living.

I'm no heroic high-flyer,
No dashing, half-craz'd versifier,
Whose noddy, crack'd by dissipation,
Madness mistakes for inspiration—
Ne'er held extatic interviews
With ranting, rattle-headed muse
With draggled dress, and slipshod shoes,
Who blows up poet's fire, they tell us,
More potently than blacksmith's bellows;—
Fell never dismally in love
With dainty duck, nor ditto dove,
Of mortal or immortal breed,
To tune to rhapsody my reed—
Have scarcely skill to make one single
Line with its next successor jingle;
But *Custom* orders me "in spindite
Of nature and my stars," (I flit)
A poor, plain, dull, dish-water mess,
To be yclep'd *New Year's Address*—
To mount my Pegasus, although
The jade is duller than a horse,
And make him budge: as when in banter
A founder'd horse is forc'd to canter,
By dint of cruel whip and spur,
He strives his sorry stumps to stir,
Yet sprawls, while every limb cries, quarter,
Like lobster plung'd in boiling water!
So my poor broken down old Pegasus
Won't move one inch without a plaguy fuss.
Yet I, by Fashion's spell, am bound
To pace this hack o'er hacknied ground,
And try more modes than one can count
To mount him first, then make him mount!
A school boy too, to sport inclin'd,
Must drag his kite against the wind,
A long way ere he makes it rise
To SCRAPE ACQUAINTANCE WITH THE SKIES!

'Tis true, that now and then I dream
Of making verses go by steam,
In strains magnificently flowing,
When Perkins' engine's well a going;
But, though this would be mighty pleasant,
It can't so well be done at present.

Since well I ween my lagging lays
Will never win the sort of lays
Which crawls the dealer in sublime,
I'll give plain common sense in rhyme;
An article, which nowadays
In our most fashionable lays,
Is rare as roses full in blow,
Blushing under a drift of snow.
I'll set forth manfully, but meekly,
What useful things I offer weekly,
Then leave it to your liberality
To give, according to their quality,
Some trifling kind of compensation
For services in my vocation.

Without pretence to brilliant parts
I lecture on the useful arts,
And, minding what I say, precisely,
You'll, probably, live long and nicely.
My sound homed-dam'd discourses
Will add much more to your resources,
Should higher stand in life's account
Than all the fam'd Pindar Mount,
Nine Muses and Acacia rill,
(Not big enough to turn a mill.)
And even Apollo's self appended
If all should be at auction vendid.

I trace the art to which we owe
All that is worth a strain below—

Great art of all arts and the science
On which all others place reliance.
The base of all, in Church or State,
Or social life, that's good or great.
For should our Agriculture stop,
Society must shut up shop;
Our brightest bellies and beaux might please
Inhabitant caves and trunks of trees;
On roofs and acorns dine like shoats!
And sup on buds and leaves like goats!
Wood-chucks would burrow in State Street,
And gaunt wolves prowl where Merchants meet!
Churches by catamounts be haunted,
And gruff bears growl where hymns are chanted,
Owls hoot the key, with pipe sonorous,
And croaking crows, caw, caw, the chorus!

I publish our good farmers' feats
In raising cabbages and beets,
Pumpkins and corn, wheat, flax, and hops,
And other most prodigious crops!
And state the means by which, if wise,
You'll even go and do likewise.
I also tell you what procedure
Will make you famous for a breeder
Of nice neat cattle, sheep and swine,
Thus make you qualified to shine
Among such patriots as those
Who organized our Cattle Shows—
State how those prizes to obtain,
Which human beings, if humane,
Had ninety-nine times rather gain
Than all the strifes with sword and gun
The greatest warriors ever won;
Whose brightest bays by tears are water'd,
And steep'd in blood of thousands slaughter'd
Whose trumpet-tones of triumph are
Mix'd with the moanings of despair,
While widow's wails and orphan's cries
Appeal for vengeance to the skies!

I tell what manufactures rare,
Wrought by the fingers of the Fair,
Strengthen affection's silken ties,
And make our heart the only prize
Which love and duty can regard
As adequate to their reward.

We farmers, and our occupation,
Compose the BACK-BONE of the nation;
Without the aid which we are giving,
Grandeur might whistle for a living—
Lawyers could not get bread and cheese,
And much less beef, by way of fees,—
Physicians must their badges doff,
For lack of folks to doctor off,
And Merchants and Mechanics might
To Arts and Commerce bid good night.

The Agriculturist supports
Our Judges, Justices and Courts;—
Without his aid good Uncle Sam
And Co. would all go o'er the dam!
Our famous and puissant Navy
Must dowse its peak to Admiral Davy;—
Our gallant army go to pot
Before they'd fir'd a single shot;
Our Fortresses be mann'd by owls,
Buzzards and other ugly fowls—
Our Statesmen grand, on dairies cramming,
Would be sad spectacles of famine:
And all at Washington now resident
From shoe-blacks, quite up to the President,
As well the leaders as the led,
Would lack even Johnny-cake for bread;—
The whole, including either House,
Must then betake themselves to browse,
Like quails in some adjacent wood,
Or starve, alack! for lack of food!

If farmers fail, like Adam's fall,
Their fate's the destiny of all;
For as old Atlas bears the pack
Of all the Heavens upon his back;
The farmer, by his care and pains,
The sublimary world sustains,—
And if the Cultivator stumbles,
The whole wide world to ruin tumbles!

But I have done, and done my best
To prove how great the interest

Good people of all ranks should feel
In what promotes the farmer's weal.
It follows thence, if worth be priz'd,
A paper should be patroniz'd,
(Dear as the apple of the eye,)
By every mortal low or high,
Which goes to aid that occupation
Which lays the only firm foundation
Of all enjoyment, every blessing—
All, all on earth that's worth possessing.
I humbly hope your Honors will
Not let its path be all up hill!
And give those wheels a little oil
Which at the best are turned with toil
Of mind and body—great expense,
Requiring cents as well as sense.
I hope your Honors, too, will make it
Agreeable for those to take it,
Who some how do not seem to see
How very useful it must be
To every body in the nation,
Of every rank, sex, age, and station.
January 1, 1824.

MISCELLANY.

We are authorised to state, that Doctor Conrad Troost, of this city, has discovered two varieties of the mineral called *Yenite*, or specimen brought lately by Major Ware, from Rhode Island. This substance was, heretofore, for only in the celebrated iron mines in the Isle of Elba. Every day furnishes proofs of great extent of our mineralogical resource and it is with pleasure that we anticipate a publication of a memoir on this subject, by Doctor Troost, in the Transactions of the Academy of Natural Sciences.—*National Gazette*.

The Secretary of a celebrated agriculture society in England, some years ago, in his report for improvement and not being overburthened with understanding, sent an order to a bookseller, for Mr. and Miss Edgeworth's Essays on Irish bulls, for the use of their society, to assist the members in improving the breed of cattle.

Amazing Increase.—Three fine acres of wheat will be reaped in a few days, by John Paddon, of Plymouth, the accumulated produce of a single chance grain, which grew in his garden about five years since.—*Eng. p.*

Ashes.—A correspondent informs us, from his own experience and the opinion of the best farmers, he is satisfied that a bushel of grass ashes is worth a bushel of corn, to put on clover, grass, or a garden; and he is surprised that any person should continue the practice of selling ashes for pot-ash, at the trifling price 8 or 10 cents a bushel.—*Hampshire Gazette*.

Among the bills reported in the Legislature of South Carolina, now in session, is "An Act more effectually to prevent the pernicious practice of Duelling." [This bill provides that persons fighting Duels, shall be guilty of Felony.]

\$381 have been collected at Albany for sufferers by fire in Maine.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

NEW ENGLAND FARMER.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

OL. II.

BOSTON, SATURDAY, JANUARY 10, 1824.

No. 24.

HORTICULTURE.

Following articles are from a gentleman, who has followed experimental to theoretical knowledge, in horticulture, and has put in practice what he inculcates. We hope that those who cultivate small tracts of ground in the vicinity of large markets will give particular attention to the subjects here discussed, and derive such advantages from the information contained in these Essays as we are sure will best meet the views of the writer.

FOR THE NEW ENGLAND FARMER.

I apprehend that too little is thought of successive crops the same year, perhaps little of the practicability of raising them. Though almost the whole of a garden two crops may be raised, in considerable parts of the year, without either crop receiving any considerable injury by it, while the most will be essentially benefited. And this may be effected with a little if any additional expense of manure, especially if the land be dry and sandy. The reason why little if any more manure is required than for one crop is that the ground is heavily covered, or shaded so much of the time, much less of the richness of the soil, and the better parts of the manure are carried off by evaporation, or destroyed by chemical changes. I mention a few successions as specimens for those who have not much ground to till; successions which have been virtually followed for several years with the most encouraging success.

Between the hills of corn may be sowed lettuce, cabbages, and things of a similar nature, all of which will be out of the way when the corn is sufficiently large to require the space they occupy. Then about mid summer set out, or plant, in or between the hills the same corn, French turnips, Ruta Baga, or Dutch turnips, which after the corn is removed will have time to arrive to good perfection. Between the hills of cucumbers, melons, &c. rows or hills of low peas, which will ripen before the vines run much. And as the vines decay set out cabbages or sow English turnips. When peas are sowed, which run up quick, radishes may be raised; and as I mentioned in a former communication, parsnips, which will, in this way make the third crop. Various other successions might be mentioned; but will serve as introductory, to those who are disposed to make the experiment. It may be proper to observe, that all this may be done not only under the highest state of cultivation, but which is only in what may be called a second state. And by the way, I will observe that persons wish to have their vegetables to be a fine relish, and to be nourishing and healthy, they must never manure them to ex-

ON HOT HOUSES AND HOT BEDS.

2. Hot houses and hot beds in their proper and appropriate use are good things—Away from this they are not to be tolerated. Their legitimate use is to secure the growth and perfection of those things, which in any particular climate could not be otherwise enjoyed. But when they are used to secure particular products out of season, they diminish instead of increasing the means of good living. A person for instance, who will take a little pains, may have his cellar filled, and his table ornamented with a great variety of fine fruit and tasteful vegetables, and all in season in the month of January at an expense not essentially differing from what it costs to secure a half dozen hot bed cucumbers, which nobody really wants at that season, and which nobody of uncorrupted taste would ever eat, were it not for the most ridiculous of all reasons, that they are out of season. The worst evil, however, is, that having them out of season, little pleasure is derived from them when in season, and when, prejudice to the contrary notwithstanding, they are a most pleasant and healthy refreshment. Every thing is beautiful and good in its season. Expense and labor should be directed to increase the number and enlarge the variety of such things as are good for food, and pleasant to the eye, but not in procuring out of season what God in his great goodness enables us by the warm influence of his own sun to have in great perfection. The sun and kindly influences of the heavens should be permitted to do what they are able to do. And with respect to what can be raised, our exertions should be directed to increasing the number and multiplying the variety, and bettering the quality, of vegetable products, not in forcing them upon ourselves, when they are not really wanted, and when from their meagre appearance, had they sense, they would be ashamed to exhibit themselves on our tables.

WEEDS.

3. Were you not Mr. Editor, acquainted with my little lot, I should not incline to write, what I am about to send you. But, you know my garden is not like the field of the sluggard, all grown over with weeds, though you know I view them in a light somewhat different from the generality of those, who delight in rural employment. That instead of considering them as evils only to be dreaded, I regard them as a kind provision of a wise and good Providence, designed not only as a wholesome food for many of his creatures, but also as a covering for the earth to secure it from the great heat of the Father of Day, when without any interruption he is permitted to pour his rays on its naked and mellow surface. Not to counteract the wisdom of the Best, my way is, after preparing the ground and putting in the seed to let the weeds spring up and grow, taking care only to keep them out of the rows and hills, and removing them as they interfere with the growth of vegetables. By this means the earth is early shaded, and a quantity of food raised for swine or cattle surpassing what any person would at first imagine. And what, perhaps, will not till trial is made be re-

dily assented to is notwithstanding true. If the experience of four years is sufficient to satisfy me in judging, a garden is kept in such a state as to have the vegetables grow well with less labor than it can by destroying the weeds as soon as they spring out of the ground. But while I would encourage the growth of weeds to protect the ground, and thus help the crops, nothing can be further from my intention than to countenance the idleness and neglect of those who suffer the weeds to choke or shade the plants. All I maintain, is, that weeds are good servants, but like fire they are bad masters; they must be kept under, but not exterminated. They must be made to hold their proper place and do their proper work, and subserve their proper end. If they are entirely destroyed they can do neither. And who will believe that so large a portion of the works of God were made in vain. If a person has a regard to the profit of his horticultural labors, and his circumstances will allow of his doing things at the most proper time, he will permit the earth to clothe itself with these light garments, which nature has provided in anticipation of those which she intends for her more staple and substantial dress.

Another advantage from this practice is the weeds afford a food for the innumerable insects and worms with which the air and earth are at that season filled. And if they do not entirely protect the rising plant from the ravages of these insects, and worms, they in a considerable degree relieve them from the injury they are liable to receive from these destroyers of vegetation.

One considerable objection to this mode of cultivation will present itself to the mind in the appearance a field or garden will exhibit. This, however, in part arises from the influence of imagination. A garden overrun with weeds is, to be sure a disagreeable sight. But this is the case, not because the weeds themselves are destitute of beauty, for many that go under this name are among the handsomest of the vegetable world; but because, from association they carry the mind to the bed of the slothful, who prefers a little more folding of the hands to sleep, to the labor to which the appointment of Providence calls him. When it is perceived that these are drawn into the service and subjected to the control of man, and are made to subserve his interest, to hold their proper place and do their proper work, they immediately appear to become what they really are, a part of that creation, which God pronounced, and all wise men have found to be good. They become indeed the more pleasant, because they are as it were, redeemed from what has generally been considered the wild and unprofitable part of creation, and offer one more proof that where God works, nothing is made in vain.

REMARKS BY THE EDITOR. It will be allowed that the ideas suggested in the above are not only novel but contradictory to the general current of agricultural authority. Writers on husbandry direct the farmer and gardener to wage ceaseless war with weeds and destroy them if possible while yet in the seed, before they have begun to vegetate. And we believe for common prac-

New England Farmer, Vol. 1. page 151.

This observation is doubtless well founded. Sir John Sinclair, says, "when a large portion of dung is the vegetable is forced so rapidly, that it is not in flavor. A moderate quantity of dung produces a better quality; but vegetables grown luxuriantly on a fresh maiden earth, are the sweetest. In all the leaves of the brassica or cabbage tribe are so superior in quality as to be nearly trans-

—Editor N. E. Farmer.

ice, and farming on a pretty extensive scale it is best for the cultivator to destroy weeds when he can most easily effect their destruction. If they are made protectors of the ground against the rays of the sun, they are apt to monopolize the soil to the exclusion of more valuable vegetation. Still we agree with the writer that the soil should never in the summer season, be destitute of a vegetable covering. The action of the sun on the surface of the soil in warm weather disengages and dissipates the volatile and gaseous products which constitute its fertility. This is in a great measure prevented by keeping the ground constantly covered during summer with a vegetable carpet. It is better that this carpet should be composed of vegetables of little value than to suffer the earth to remain without covering of any kind. But at all events, weeds should all be cut down or dug up before their seeds have become ripe, and if their races should become extinct, it will be easy to find substitutes to shade the soil—such as spinach, lettuce cabbage plants, &c. the seeds of which cost but little, and their produce is more valuable either for shading the soil, or furnishing food for man or beast.

From the Concord Gazette.

The Trustees of the Society of Middlesex Husbandmen and Manufacturers, report for the information of the Society, that at their annual meeting at Concord, Dec. 31, 1823, they awarded to Col. Joseph Valentine of Hopkinton, the premium of \$10 for having raised the greatest quantity of Indian Corn on one acre of Land, being 127 bushels and 3 pecks. —Col. Valentine gives the following account of the mode of cultivation adopted by him, viz:

The quality of the soil is a deep yellow loam, situated on a western declivity and naturally moist. The land has been improved for mowing six years last past, and until the last year it has yielded very heavy crops. In July, 1822, the crop of hay falling below the produce of former years, I thought it expedient to stir the ground. In August following the ground was broken up, and in November it was harrowed and cross ploughed. In the spring of 1823, it was again ploughed and harrowed, and twenty loads of green barn manure, spread equally over it and ploughed in. It was then furrowed in rows about three feet and a half apart, with a large horse plough, the plough going twice in each row to make a deep channel for the compost manure, and also to leave the seed when planted lower than the general surface of the ground. The rows thus prepared, were filled with twenty loads of barn, hog-yard, and night manure, well mixed and pulverized with Smithfield lime: the manure was then levelled, and the kernels of seed placed about ten inches apart width-wise, and four inches lengthwise in the rows and lightly covered with fine mould. The seed was the yellow twelve rowed corn, which was soaked in a strong salt-petre brine, twenty four hours and then spread, sprinkled with quick lime and raked over until completely coated with lime. It was ploughed twice and hoed three times. At the last hoeing, the first of July the suckers were pulled out, and in the fore part of August, the suckers were again pulled away and the false stalks cut up. In hoeing the corn I was particularly careful to loosen the soil and remove the weeds without raising the earth about

the stalks as I had usually done. The stalks would average from nine to ten feet high, and were cut the first week in September. The first week in October, the corn was harvested, and carefully measured in baskets by two men who had assisted in cultivating the crop. I directed the same men to take each of them a basket and fill it with ears in the same manner, as when they measured the whole, and to shell and measure the quantity of shelled corn obtained from each basket of ears; the amount of shelled corn from each basket of ears was the same, viz. nineteen quarts, and when turned together and measured, the result was one bush. six quarts and a fraction over, from the two baskets. —By computing the produce of the whole acre from the quantity of ears as measured in the basket, and the amount of shelled contained in a basket of ears, the result is one hundred and twenty seven bushels and twenty one quarts of shelled corn. The field in which the above acre was measured contains three acres, one half of which was planted with seed prepared as above described; the other half was planted with seed in its natural state. The corn in every part of the field came up well, and as all the ground was cultivated and manured alike, there could be no difference in the quality of the soil to invite or repel insects and vermin. But that part which was planted with seed in its natural state, at least one sixth part of the blades were eaten off and destroyed by worms; while in the part planted with seed soaked in brine and coated with lime, not a blade was discovered that had been attacked by them. This is the first experiment I ever made to prove the utility of securing corn against the ravages of worms, by any process applied to the seed. Perhaps the mode above described and pursued by me will not always be attended with the like success. It may however be the means of exciting the attention of others who have more leisure and ability than myself to discover and apply a certain remedy for so great a nuisance to the farmer.

EXPENSES OF CULTIVATION.

Four Ploughings,	\$5.00
Harrowing	1.00
Manure, 40 loads	30.00
Furrowing	75
Seed	50
Planting	4.00
Ploughing and hoeing	7.50
Cutting stalks	3.00
Harvesting	4.00
	\$55.75

The value of the stalks and fodder I consider equal to a ton and a half of English hay.

That they also awarded to Col. Valentine the premium of \$10 for having raised 37 bushels and one peck of wheat on one acre of land by the following mode of culture.

In the spring of 1822, it was ploughed and planted with Indian corn, forty loads of manure were spread and laid upon it, and the crop produced was one hundred and sixteen bushels and twenty-eight quarts of corn, well dried and fit for use. In the spring of 1823, as soon as the ground was fit for ploughing, I had it ploughed and harrowed twice; three bushels of Gilman Wheat were sowed on one acre and a few rods, and ploughed in. I then sowed twelve pounds of clover, and half a bushel of herds grass seed, spread one hoghead of slacked lime upon it,

and harrowed it with an iron harrow. The wheat before sowing was washed clean in clear water, then soaked forty-eight hours in strong lime water, then laid on a dry floor and slacked lime sprinkled upon it and frequently stirred until it was covered with lime. In the month of July, the land on which the three bushels of wheat was sowed, was measured and found to contain one acre and a few rods over; the number of rods exceeding an acre was stalked off, and the wheat growing, reaped and threshed by itself, and the produce was between one and two bushels. The acre was reaped and bound with long rye straw, and found to be seven hundred and sixty-two bundles, making fifty shock, and twelve sheaves; which when threshed, winnowed, and measured, produced thirty seven bushels and one peck. The quality of the grain was excellent, and weighed six pounds to the bushel, not a kernel of smut or burnt grain was discovered among the whole.

Per order of Trustees,

N. BROOKS, Rec. Sec.

Reports of the several Committees of the Worcester Agricultural Society.

REPORT No. VI.

Committee on all other Manufactured Articles.

Stephen P. Gardiner, of Bolton, Chairman; Samuel Mixer, of New-Braintree; Benjamin Read, of Templeton; Royal Keith, of Grafton; Seth Davenport, of Andover.

The Committee appointed by the Trustees of the Worcester Agricultural Society, to examine all Manufactured Articles besides Cotton Wool, Flax and Silk, have attended to the duties assigned them. A great number of excellent lots of Butter and Cheese was offered for examination, too many to particularize, and perhaps unnecessary to mention, all the owners' names in this Report. It is but justice to say, except two or three lots, it was all of a superior quality; and it was with some difficulty that the Committee could satisfy themselves who were entitled to premiums. Other articles which came under our notice, did not equal the expectations of the Committee. They however commend the following premiums.

To Levi Goodale of West-Boylston, for the best Butter, &c.

To Ebenezer Dunbar, of Leicester, for the best, &c.

About 15 lbs. of superior Butter, in cake for neatness and flavor was not exceeded by any, and if the funds of the Society will justify it, the Committee recommend to Ebenezer Moor of Worcester, the owner, a premium of \$3; William Tufts, of New-Braintree, for the best Cheese, \$10; to Elisha Matthews, of New-Braintree for the next best, \$5; to Chester Patch, of Leicester, for a set of Machine Casts: to William Stocumb, of Northborough, for the best dressed Calf-Skins, \$10; to Phineas Davis, of Northborough, for Sole-Leather, premium, 5; to Joseph Griggs & Co. of Milbury, for Morocco, 2d premium, \$3; to Simeon Hathaway, jr. of Sutton, for the best Ox-Yok, \$6; to Andrew Duxton, for the next best do, \$3.

N. B. Mr. Davis, for Sole-Leather, and Mr. Griggs, for Morocco Skins, had no competitors. Their articles, though good and well manufactured, were not extraordinary; and in the opinion of the Committee were not entitled to the first premium. A great variety of articles, both

gant and useful, were noticed by your Committee, for which no premium is offered; many of them deserve attention, viz. A number of elegant and highly finished Hats, by John P. Tell & Co.—some handsome Window-Blinds, Miss Kitteridge—an elegant Trunk, by Daniel Walker, of Brookfield—an ingenious Machine, by John C. Jenckes, of Providence, for moving sick and lame people, with ease to patient, and convenience to the assistant—superior pair of Tailors' Shears, by Elias Ayer, of Lancaster—an elegant box of Needle-Work and Painting, by Misses, in Miss May's school in Worcester—some fine Turquoise Fans, Feathers, Plumes, Wreaths, &c. Mrs. Daniel G. Wheeler, of Worcester—a and improved patent Straw-Cutter, by Mr. Lord, of Vermont—a great variety of Straw Grass Bonnets, many finely wrought, and showing taste and judgment—a lot of fine shoes, which had been greatly improved in two years, by proper attention, by Isaac Bowditch of Lancaster—one well turned and comely finished Nail-Hammer, by Mr. Woodbury Sutton—one Cast-Iron Plough, much improved by W. A. Wheeler—and Mr. Howard's high and Harrow for weeding Corn and Vegetables.

Which is respectfully submitted.
STEPHEN P. GARDNER, *per order*.

REPORT No. VII.

Committee on the Ploughing Match.

Thayer, of Uxbridge, Chairman; Joseph Sumner, jr. of Shrewsbury; Paul Dudley, of Douglas; John Whitney, of Princeton; Rufus Porter, of Worcester.

The Committee on the Ploughing Match have been highly gratified to find an increased number of competitors for premiums, in this interesting and very important part of the Exhibition, this day witnessed. And although gratified, they have very much increased the difficulty of labor of those who are called upon to discriminate and reward those who excel, agreeable to the rules and regulations of this Society. The Committee regret, very much, that the ground selected for ploughing proved different from what had been anticipated. Instead of a deep loamy soil, as the surface indicated, it was so full of gravelly loam and round stones, (such as Farmers usually call cobbles), that it was with some difficulty that the ploughman could keep his plough in the ground, and at a proper distance from the foregoing row. Agreeable to notice, the ground had previously divided into lots of an eighth of an acre each; twelve competitors were present in teams, consisting of one yoke of oxen each, and new lots as follows;

No. 1. Nathan Heard, jr. of Worcester, ploughman, John Armstrong, driver—work performed in 23 minutes 30 seconds.

No. 2. John Sherman, 2d. of Sutton, himself ploughman, Daniel Marble, jr. driver—work performed in 22 minutes.

No. 3. William Eaton, jr. of Worcester, himself ploughman, no driver—work performed in 21 minutes.

No. 4. Benjamin Woodbury, of Sutton, himself ploughman, 3d. ploughman, no driver—work performed in 21 minutes 30 seconds.

No. 5. Stephen Marsh, jr. of Sutton,

Hiram White, ploughman, Stephen Marsh, driver—work performed in 21 minutes.

Lot No. 6. Holloway Bailey, of Northborough, himself ploughman, Paul Newton, driver—work performed in 20 minutes 30 seconds.

Lot No. 7. Luther Whiting, of Sutton, himself ploughman, Royal T. Marble, driver—work performed in 19 minutes 40 seconds.

Lot No. 8. Joseph Dudley, of Sutton, himself ploughman, John Adams, driver—work performed in 24 minutes 20 seconds.

Lot No. 9. Ward & Rice, of Worcester, Newell Rice, ploughman, no driver—work performed in 19 minutes.

Lot No. 10. William Henshaw, of Leicester, Benjamin Watson, jr. ploughman, William Henshaw, driver—work performed in 20 minutes.

Lot No. 11. Silas Dudley, of Sutton, himself ploughman, Samuel Taylor, driver—work performed in 23 minutes.

Lot No. 12. Free grace Marble, of Sutton, Samuel Sibley, ploughman, Free grace Marble, driver—work performed in 23 minutes.

Your Committee, in the discharge of their duty, have been extremely desirous to do justice to all the competitors, and to all the other members of this Society. And notwithstanding the competitors were unfortunate in their ground, the Committee are of opinion that there was not that improvement in the work which they and the public had reason to expect: and as the great and professed object of Ploughing Matches is improvement, and to extend a practical knowledge of the art, the Committee could not, with justice to their own judgments, and the duty they owe to this Society, recommend the full amount of premiums to those who they considered to excel, that the Trustees had empowered them to do, but have recommended one half that sum.

First premium to Free grace Marble—Plough \$5; Ploughman \$2, 50; Driver \$1, 50.

Second premium to William Eaton, jr.—Plough \$4; Ploughman \$3; being no Driver.

Third premium to Nathan Heard, jr.—Plough \$3; Ploughman \$1, 50; Driver 50 cts.

Fourth premium to Silas Dudley—Plough \$2; Ploughman \$1.

N. B. The Trustees afterwards awarded full premiums, instead of half premiums, as recommended by the Committee.

Per order.

JOSEPH THAYER, *Chairman*.

From the American Farmer.

Mr. Orton, surgeon, 34th regiment, has explained the cause of fowls dying so often on ship-board. It is want of sharp cornered gravel to triturate corn in the gizzard. This he discovered by dissecting one of the dead fowls.—"The next step was to take advantage of the information thus gained; but the maxim that 'knowledge is power,' seemed likely to meet with an exception in this instance; for we were many hundred miles from land, and there appeared little chance of finding any substitute for proper gravel on board the ship. Inquiries were made for a stone, by which the experiment might be made with a few of the fowls; and it was soon found that abundance of a rock, resembling granite, had been taken on board as ballast at St. Helena. A quantity of this was immediately broken up into pieces, about the size of split peas, and given to the poultry.

They swallowed it eagerly. The sick birds were collected, and a quantity of the specific placed before each; and though most of them were unable to stand, they devoured it with eagerness, several in quantities of a tablespoonful each. They all recovered except one. In short the mortality from that time entirely ceased, and the remaining poultry (by far the principal part,) instead of dying, became excessively fat. Fowls, when allowed to run about, are observed to be very nice in selecting the pieces of stone which they swallow. In many of those which I dissected, I found pieces of broken earthenware, chosen doubtless on account of their sharp edges. I would recommend hard stones to be laid in for fowls on board ship, and broken up, instead of natural gravel, which is commonly more or less rounded. River or sea sand, or gravel, is evidently useless."

A Bear Story.—Lemuel Martin, Esq. of Sullivan county, informs me, that on the 27th ult. Mr. William Fisk and his son, while hunting, in the town of Rockland, in that county, discovered the track of three bears, which they pursued about three miles to a den. They urged their dog, but in vain, to enter and attack the ferocious beasts. It being near night a fire was built up and they watched until next morning, when they collected a number of their neighbors, and about twenty dogs, three only of which had courage to enter and attack the bears; and after a serious fight, two cubs presented themselves at the mouth of the den and were shot, while the old bear kept possession of her fastness. The dogs satisfied with their partial conquest, could not be prevailed on to renew the fight, Mr. Fisk got his Green Mountain spunk up, and determined not to give up the victory. He accordingly assisted by Mr. William Gray, with a light, entered the cave crawling more than fifty feet, discovered the glaring eyes, and heard the threatening and gnashing of the teeth of his potent adversary—he discharged two rifles, the smoke drove them from the cave. On entering afterwards, they discovered that their adversary had expired, and they drew from the cave (sixty feet) an enormous she bear.

The Himalaya Ridge.—A long paper in the Asiatic Researches, vol. 15th. by Messrs. Hodgson and Herbert, gives the height of a number of the snowy peaks of the Himalaya ridge of mountains, from a survey—from which it appears that the highest of these peaks has an elevation of 35,589 feet, or 4 m. and 3 qrs. This is 3 qrs. of a mile greater than the height of Chimborazo, the most elevated of the Andes.

The following curious circumstance is stated in the Farmer's Journal:—A farmer bought about thirty pigs, and immediately put them all up to get pork. Their food was boiled potatoes. In a short time a distemper appeared among them, and about twenty died. The potatoes given to the pigs belonged to a crop of ten acres on light land; and in harvesting them, a great many which had been long exposed to the sun, and weather, were of course, thrown aside for pig food.—Potatoes so exposed acquire a poisonous quality, the upper side turning green, and having all the appearance and taste of green coppers—that is, the oxide of iron; the potatoe contains a portion of iron in solution, which attracts the oxygen of the atmosphere. The potatoes in the retail shops in London are much injured by lying long in the light air: so that where the sale is slow, they are at least unpalatable and unwholesome.

Proceedings of the Nova Scotia Provincial Agricultural Society.

An Anniversary Meeting of this Society was convened at Halifax on the 1st of December last, and after transmitting the formal business which the occasion demanded, the following proceedings took place, as stated in the Acadian Recorder of the 6th of Dec.

The Vice President stated to the meeting that the disposal of the money which lay in the hands of the Treasurer was now the subject of their consideration, and he requested that the Secretary, who probably had revolved the question in his mind, should now publicly propose what he had to offer.

Mr. Young rose and said, that the large balance now over was more than adequate for all the demands of the Society, and that £200 ought to be disposed of in some way or other. It ought either to be lent at interest upon good personal security in order that it might be forthcoming whenever the exigencies of the Society required it, and it might be vested in some agricultural speculation which would at once promote the general interest of the farmer, and be directly conducive to the benefit of the town. If the latter plan were adopted he had turned over in his own mind those objects which stood in need of encouragement, and were of such paramount importance as to justify the application of so large a disposable sum. He would not attempt, at present, to go into any minute details, because the sentiments of the gentlemen present were as yet unknown—but he would beg their indulgence, while he slightly touched those subjects which occurred to him as worthy of immediate attention.

A part of this balance, he thought, might be judiciously employed in premiums for clearing and improving the land which lay within a circle of three or four miles around the capital.—It was well known to the meeting that the natural obstructions which presented themselves both in the peninsula and at Dartmouth were of a formidable nature, and sufficient to damp the zeal even of the most enthusiastic improver. From the number of stones which encumbered the surface and the native sterility of the land itself, every acre required an outlay of from £40 to £50 before it was adequately cleared and manured for a first crop. Such a heavy expense therefore would not be voluntarily incurred without a powerful excitement, more especially when capital at the present moment could be profitably invested in commercial undertakings.—In order therefore to invite capital from commerce, it was necessary that this Society should hold up some bounty for the improvement of every acre. This could be deemed no waste of the private funds, when the vast importance of cultivation in the vicinity of the town was duly appreciated. Every acre of land rendered arable was supplying our market with those vegetables and roots essential to the means of subsistence, and must be looked upon as an advantage not only to ourselves but to our posterity. Every rod of improved ground opened up a new source of production for the supply of our daily wants, which were increasing in number with every increase of our population.

Another object which he would recommend to the Society was the encouragement of Oatmills in the neighborhood of the town. Meal

was fast rising in demand with all classes of the inhabitants; and strange it was to tell that no mill for manufacturing it had been erected in this vicinity. The single district of Pictou could boast of 22 oatmills, which had risen during the last four years as if by enchantment; and yet the metropolis of the province could not number one amidst all its public improvements. This was felt as a want not only by the farmers in the immediate vicinity, but throughout the whole province; because the immense quantities brought in there for sale every spring and fall, lay as dead weight upon the market, and labored under great and serious depression. But were mills only erected, our merchants would purchase these oats on speculation, would manufacture them at their convenience, and then deal them out in the shape of meal, according to the calls of the consumption.

The last object which we would bring under their notice was some method of encouraging the curing of beef and pork. The Directors, as they all knew, had warmly recommended this subject, but without effect, to the provincial Legislature; and it would now be becoming in them to testify their sense of the utility of the measure, by offering some bounties with a view to its encouragement. Had the Legislature adopted the recommendation of the Central Board, bounties would have been offered to the curers of salt provisions, whether they resided in Annapolis, Pictou, Halifax, or any other part of the province: but if the private funds of the Society were to be appropriated to this object, it became a question of expediency how far the bounty should be extended, or whether it should be confined to the merchants in the capital. He surely did not need to press with much earnestness the imperious necessity of relieving the farmer in some way or other. Beef at present was daily selling at 2d. and 1½d. per lb.—a price so utterly incapable of remunerating the raiser, that it must obviously tend to weigh down the agricultural interest of the country. Beef, weight for weight, was now as cheap as oatmeal; and he would put it to their knowledge whether the farmer could produce the one as cheap as the other. A handful of oats thrown carefully by the sower, and covered with a single turn of the harrows was an easy and little expensive process; contrasted with the care of raising a calf, of nurturing it for two or three winters, and of finding it with grass through the summer before it was fit for the butcher. Beef per lb. should at all times be double the price of oatmeal. Let any man search all the records of farming, the tables of the price of provisions which had been published in England or France, nay, either in the old or the new world; and he would find it to be an invariable law, that whatever is the rate of bread, butcher meat is double that rate. But here that ratio of relative value was entirely subverted; and we had the anomalous appearance of beef sinking every autumn below bread; and thus entailing on the agricultural body a manifest and prodigious hardship. He trusted that this order of things would be soon reversed: as it brought us within the operation of the great law which regulated the depression and elevation of human affairs—and which was this; that whenever any article descended much below its value, its production was proportionably discouraged, and

its future advance in value rose beyond the point of equilibrium. Three pence half-penny and four pence per pound for beef were perhaps the fair price at the present moment, compared with that of bread, and accordingly we had many years experienced that butchers' meat in May and June started to 6d. and 7d. per pound and thus balanced in some measure the depressed rates of November and December. It appeared that while the poorer farmers suffered grievously in the fall, the community generally reaped no benefit; because the glut was invariably followed by a corresponding scarcity. He, therefore, submitted to the present meeting, how far it would be proper by a few judicious bounties, to induce our wealthy merchants to embark in the salt provision trade.

Judge Haliburton addressed the chair in reply. He stated frankly that for his part he would not sanction the lending of the money. The members of that Society had contributed their quotas for the purpose of improving the agriculture of this province, and that great object should in no instance be lost sight of. The interest of 12l. a year would weigh light in the scale, compared with the disposable balance which was now in the hands of the Treasurer. He approved of the objects which had now been recommended to their attention, and particularly the encouragement of oatmills. He had now become almost an article of daily food in the capital and the means of manufacturing well deserved the care of this Society. On during two seasons of the year were always thrown into this market so plentifully as to suffer a great depreciation in value. He himself had been offered them the other day at 1s. 8d. per bushel; but in the course of three months he knew and anticipated that they would rise to 3s. Were mills of that description self-motion here, the superabundant quantity would now be profitably carried off, and converted into a cheap, useful and healthful food; and he therefore heartily concurred with the Secretary in opinion that part of the private fund might be wisely employed in encouraging the erection of one or two oatmills.

Walter Bromley, Esq. said, that he thought there might be some other objects than those enumerated which deserved the countenance of this Society. On former occasions he had heard with great pleasure the Attorney General expatiate on the wool of Nova Scotia, which was the necessary staple of our domestic manufactures. He had lately tried an experiment of this kind; in which he had embarked from £40 to £50; and he did this in order to induce good habits among the young. He had often heard the ladies of Halifax complain of the want of industry in their servants—an evil which could not be remedied, till the raw materials of flax and wool were properly protected, and till a taste for industry was given to the rising females. He had lately employed 32 spinners of wool in school and 7 women outside—13 knitters in school and 15 outside—making sixty seven in all employed in the new manufacture: and the socks were in such big demand, that he could by no means answer their orders. Notwithstanding the high price of wool he was enabled to sell these per pair 2s.; and he had brought and now presented a specimen of them on the table for the inspection of the meeting.

The Attorney General next claimed the attention of the meeting, and for a few moments tested their patience. The question before him was the disposal of the £200 remaining from the present funds above the exigencies and wants of the Society. He was clear that they ought to be kept untouched, and no more expended of them than the profits and interest. His institution has already laid out a great sum for the importations of implements of husbandry, which had served as models to all our mechanics in the fabrication of similar articles. A great improvement that had taken place in the machinery throughout the province must obviously be traced to this source; and he was of no other application of the money could have been productive of better effect. But although we had thus done good to the agriculture of the province, we had lost money by the transaction and diminished our capital. It should be our future policy, on all accounts, both to advance the general prosperity and save our capital at the same time. The improvement of the peninsula and the lands around the capital had been spoken of in favorable terms, and this measure certainly had his warmest concurrence. The Attorney himself had set an excellent example in his head; and nothing had so much astonished him when he lately visited his farm, to see excellent crops of wheat, clover, potatoes and other vegetables growing on a piece of land, which had once been a ragged and worn soil; and which he had often traversed in its rude state while shooting plovers. Had been in England or Ireland and there actually have fallen in with an inhabitant of the West Indies, who told him of the actual improvement now accomplished at Willowpark, he (the Attorney General) must have great faith in the success of the teller, before he could have given his assent to the credibility of the story. He was, therefore, much indebted to the Secretary of the Society for showing the capability of improving the peninsula—yet he was not going to devote the £200 to this object, because he thought that the ordinary funds of the Society were sufficient to accomplish it and that the spirit of enterprise alive. He would either would he turn these surplus funds to the erection of oatmills. These had found their way already into many parts of the province, and particularly to the eastward. From hence he saw them proceeding forward—springing round by the back of Partridge Island—and he would not be surprised though they would dash in upon Annapolis and take possession of Digby. The enemies of meal would now just say or do what they please—but it was plain to all sensible men, that it could never be banished out of the province, because it had taken firm root in it. With respect to domestic manufactures recommended by Mr. Bromley, he felt every inclination to praise the gentleman for his efforts, and thought that he could not sufficiently thank him. It was not, however, within the power of this society either to recompense or stimulate his labors. He must look to the Legislature for effectual aid. A law should be passed prohibiting the exportation of a single pound of wool; for there was not enough raised in the province to answer the ends of internal consumption. But if wool was insuffi-

cient, Mr. Bromley should add flax to his establishment; and betwixt the two he would find enough for his manufacture. He (the Attorney General) himself would engage to send him a considerable quantity of flax fit for spinning, and allow him a liberal compensation for his labor. He was truly glad to see that a spirit of manufacturing domestic articles had been lately awakened, and that it was spreading fast throughout the province. Orderly and domestic habits, often the offspring of necessity, would soon assimilate themselves to our manners, and become fixed and stationary in our country. They required from us no further nurturing, than to prohibit the exportation of the raw material as flax and wool.

He now turned to the depressed condition of our grazing system, which ought to be revived by all means in our power. This country was well adapted for raising beef, pork, butter and cheese, if proper methods were employed and a more enlightened system of rural economy adopted. But our lands, and those too, of the very first quality, were appropriated to the scythe and not to the sickle.—Our countrymen were graziers and not farmers, and this erroneous method of management had been continued and propagated for a great number of years.—according to all the most rational views which have been taken of the management of land, grazing and husbandry should reciprocally support each other and go on hand in hand. It was the plough that ought to support the cattle; and the straw of white crops with turnips and other roots should be their main dependence. But notwithstanding these pernicious habits, we must help the farmers out of their difficulties the best way we can. This Society had its foundation in liberality, and was instituted for the professed purpose of removing the pressure which weighed down the agricultural body. This was an era in our history of which we would be long proud—but the spirit in which the Society begun ought still to inform and animate all its future measures.—Our agriculture labors now under the cheap prices of beef and pork.—And to this, and this alone we could direct whatever impulse could be communicated to our agriculture by the present disposable £200. His plan would be to employ the money in an experiment, under the direction of the Society to export to the different parts of the West Indies a quantity of well cured salt provisions. He would propose a judicious committee to be appointed with full powers to manage this business.—An experienced hand must first be procured to divide the carcass into proper pieces; for all the butchers in Halifax could not cut up a pig as it ought to be done, with their whole united skill. Both pork and beef should be so separated as to furnish two or three qualities; and the prices at which these are to be bought should be fixed and known beforehand.—If the farmer could sell to others to more advantage than to the committee, let him do it, and only have recourse to their fixed prices when he cannot better promote his interest.—Every article that comes from the country—hides, tallow, beef, pork, butter, cheese, should be capable of being disposed of at a certain known rate, so that the farmer would not need as now to hawk them about town till his patience was exhausted. He would not attempt to instruct the committee in

the mode of cutting up the carcasses; but certainly he could depend upon his skill in curing them. He was much disappointed in not receiving from Mount Uniacke two pieces of beef which he had sent for and which he meant to present to day to the Society. They had been cured since Oct. 1822, and had lain in the pickle since that time; and yet both the fat and the fibre were excellent and juicy.—The committee might therefore command his services, and he would cheerfully spend three or four weeks in giving them all the help in his power. He, therefore, most earnestly proposed that a venture of this kind should be undertaken; and when he had obtained the account of sales from the West Indies, the success of the experiment would hold out a sufficient stimulus to our merchants to engage actively in this trade. Three persons should be chosen, into whose hands the £200 should be paid under certain regulations; and they ought to be instructed to buy beef and pork, cure it in a proper manner, ship it to the West Indies, and lay the proceeds of the adventure before this Society.

Mr. Bromley, in reply, stated that he had introduced flax into his manufactory and spun a good deal of it into yarn. He had lately received five hundred weight from his Lordship the Earl of Dalhousie in a present, which he was working up as fast as possible; but women who were engaged in spinning it, notwithstanding all the murmurs of the hardness of the times had the confidence to ask of him 2s. a day for their labor. He thought, therefore, that our domestic manufactures should not be neglected in the application of the disposable sum.

From the Massachusetts Spy.

Our Coal Mine.—Since the allusion which we made, some time since, to the Coal Mine in this town, we have frequently been inquired of, respecting it. We have delayed making any further statements, in hopes that such experiments would be made, as would enable us to give a full description of its kind and qualities. As yet, this has been but partially accomplished. The bed is apparently of considerable depth and of great extent, shewing itself in various places. At the place where it is now open, it appears above the surface of the earth, and may be procured in vast quantities, at an expense almost nominal. It is of the species called Anthracite, by mineralogists, and is the same kind as the Liverpool glance coal, the Rhode Island coal, and the Schuylkill and Lehigh coal. It is valuable in furnaces, forges, and for most manufacturing and domestic purposes. We have burned some of it, and find it to ignite readily, and to produce great heat. It has been burned with the Rhode Island and with the Lehigh coal, and found to ignite easier, and to burn longer, after taken from the fire, than either of them, but the specimens which we have seen, we think, leave a greater residuum than the Lehigh. As the bed is excavated deeper, it will probably be more pure.

This coal has been considerably used at the Brewery in this town, and is found to answer better than other coal for that purpose.

Hydrophobia.—The following mode of curing hydrophobia, is certainly novel, and may supersede scullap.—“An extraordinary surgical op-

eration was performed a few days ago in one of the great hospitals of Paris, upon a man labouring under the dreadful *malady, hydrophobia*. He had for some time manifested the utmost horror for liquids, and showed a disposition to bite whatever came in his way.—The surgeons of the hospital determined to try upon him an experiment which had been found successful when applied to animals.—The operation consisted in the introduction of water into the veins, by means of an incision above the wrist. The experiment fully succeeded, as the patient now takes liquids without aversion, betrays no inclination to bite, and is free from fever.

[The author of the following has laid us under great obligations by his obliging communications. It is, perhaps, an object of as great consequence to Agriculturists to state what plans and deviations from established practices do *not succeed* as to mention those which do *succeed*. Such statements may save much expense and trouble by preventing repetitions of useless experiments. Many supposed improvements have been tried over and over again, with reiterated failures, merely because those who have been engaged in each repetition of a fruitless trial were ignorant of the attempts of their predecessors. We hope Mr. Jarvis will oblige us by a continuance of his correspondence.]

FOR THE NEW ENGLAND FARMER.

T. G. Fessenden, Esq.

Sir,—In your N. E. Farmer of the —, I observed an account of a Virginia Fence with upright posts, which being at an angle of —* with each other and connected with rails, would be self supported.—As my experience of the angle required for strength, has been different from that of your correspondent, and as this difference probably resulted from the different exposures of the fences—I have thought it might be well to communicate to you the result of my experiment. In the spring of 1821, having occasion to make a considerable length of fence, I was induced from the recommendation of an agricultural friend to try the Virginia Fence with upright posts. The fence was made with cedar posts about five inches diameter and four feet six inches long, standing at an angle of forty-five degrees, and connected by sawed rails five and six inches wide, 1½ inches thick and 10 feet long, strongly nailed, spaces between rails 6 inches; the fence was not sheltered from the high winds, nor was it more exposed than in any clear and level country; in less than a week the whole length (one hundred rods on each side of a road) was completely overset, the posts supported by the rails preserved their relative situation, and made the same angles in air that they had made on the ground. I was then satisfied that the angle adopted was not sufficient, and had the fence new set on an angle of ninety degrees, this has been found to answer, and I believe a fence so built would stand a gale equal to any common fence.—The cost of 100 rods of this fence is as follows:

243 Posts, Cedar, 4 feet 6 inches long, 5 inches in diameter, at 4 cts.	\$9, 72
5467 feet, board measure, Rails 1-8 inches thick, 6 inches wide, at \$7	38, 27
4 M. Cut Nails, 20 lbs. to the M. at 7 cts.	5, 60
Setting the Fence,	10, 00
	\$63, 59

This cost might be greater or less according to the price of the materials where the fence was built.

In consequence of the fires which ravaged a great part of Maine, the past season, I avail myself of the medium of your very valuable paper to suggest to the sufferers whether it would not be well to improve the land burnt over by clearing it to the extent of their means, and by sowing the remainder with the Dutch White Clover, more commonly known by the name of the white honeysuckle.—Last spring we sowed about 400 lbs. of that seed on a tract of land burnt over the preceding summer; the land was in the same state as left by the fire, the seed was sown at the rate of two pounds to the acre just as the frost was coming out of the ground; notwithstanding the extreme drought of last season the seed took well—by the middle of July the grass was in full bloom, and afforded a fine bite for cattle. This seed was bought of Mr. Makepeace, of Cambridgeport, in the fall of 1822; I have understood he has a quantity of the same lot on hand, which if not injured by age, I can recommend as of the best quality. We also cleared up about 40 acres of the same kind of land; twenty of which were sown with oats and millet, six with English turnips and laid down with herds grass and clover, and fourteen acres sown with grass seed alone.—The grass seed took well in each case, best where sown alone, next best where sown with turnips.—The oats and millet being sown late, and having to contend against a drought severer than has been known for twenty years, gave but a light crop, on an average but little more than half a ton to the acre, the turnips gave about two hundred bushels to the acre, six hundred bushels were harvested, and about as many more were fed off by fattening cattle. With this last mode of using the turnips I was much pleased, as the whole expense of harvesting was saved—the cattle throve faster than I ever knew them to thrive in the barn, and the turnips were eaten as clean as they would have been harvested by hand. The cost of an acre was as follows:—

Clearing land, paid for by the job	\$5, 00
1 lb. turnip seed,	50
Harrowing & sowing and after sowing,	4, 00
10 lbs. clover seed,	1, 00
6 quarts herds grass seed,	75
	\$11, 25

As an offset to this was the value of the crop of turnips which could not be estimated at less than the above cost of \$11, 25, and the land was reclaimed from a state of waste to one productive either as mowing or pasture.

Encouraged by this success we intend improving the land we have had burnt over the past season in the same manner and to a greater extent. We have now 1000 lbs. of the white clover seed on hand which will be all sowed in this vicinity as soon as the ground is bare of snow—this besides insuring an abundance of summer feed of the best quality will

be a security against future fires, as the white clover is always green and will prevent the growth of moss which in a dry time is highly inflammable—by furnishing a covering for the land, it will also prevent its deteriorating as the case when the land, stripped of its natural covering, is left exposed to the sun.

With respect, &c. CHARLES JARVIS.

NEW ENGLAND FARMER

SATURDAY, JANUARY 10, 1824.

CATALOGUE OF AGRICULTURAL WORKS. We promised some time since to publish a catalogue of approved agricultural works, together with information where such books may be obtained. We have not yet been able to complete our list, although we have made repeated "calls for information" on our principal booksellers. Those gentlemen all promise to make out a catalogue of their agricultural works, but some of them have not yet found time to complete it. There is, however, a pretty fair prospect that our next number may contain a list as complete as can be conveniently furnished.

AN EXAMPLE WORTHY OF IMITATION. A gentleman writes to us that "a few farmers in this town are about forming themselves into a society, principally for improvement in our wretched practice of farming." It is our present intention to procure an apparatus for analyzing soils, and a library of some of the most valuable works we can get on scientific and practical agriculture, and domestic affairs." This contemplated association appears to accord with the Hon. T. Pickering's recommendation, expressed in his Address to the Massachusetts Agricultural Society, which as it cannot be too often repeated, we will here reproduce.

"As we have no farmers who cannot read—in order to give to all opportunities of reading, I suggest for consideration, the expediency of forming in each township in the State a farming society, of which the members should meet monthly, to converse on farming affairs—to make mutual communications of their practices in husbandry—to commit to writing every practice in common use, which may be beneficially extended—and to read and examine modern publications on the vocation; particularly those of the State Society, which the Trustees would gratuitously furnish. To these such township societies would find it agreeable and useful to add the best periodical publications, which issue from the presses of our own country, either through the agency of agricultural societies, or of well informed individuals. With these and a few other books on the subject, each township society would become possessed at a very small expense, of a pleasing and instructive agricultural library."

FASTENING FOR WINDOW SHUTTERS. A friend and correspondent requests us to state that "there has been in operation for about a year in Bradford, Mass. and its neighborhood, a Fastening for Window Shutters, and Outward Doors, which operates by its own weight, catching in little hooks, driven, one into the side of the house, and the other into the window stool; itself resembling at the end the catch of a common fastening to a door, and which has been found from use altogether sufficient. It is a convenience which any blacksmith can make, and, which, since it is not a patented thing, any person has a right to make. It can in no case, properly cost more than 12 1-2 cents, and if made in numbers not more than half that sum." These fastenings are made by Mr. Bacon, of Bedford, Mass.

* This blank, together with that which precedes it, the Editor was requested to fill with the date of the paper and the degree of the angle alluded to, but having made diligent search we cannot, at present, turn to the passage to which the author refers.

The inhabitants of this city have chosen Committees in their respective Wards to ascertain the number of persons therein subject to the small Pox, with a view to a general Vaccination.

Editor of the New England Farmer,

—In this age of improvement, as it is justly called, no person has invented a suitable Press extracting the juice of Currents. It has become very valuable to make current wine; and it is an *ex-act*, and cheap substitute for any imported wines, but of an of a Press is much felt. It appears to me that an who shall invent a cheap Press, will find a demand for the article. A FARMER.
Boston, Jan. 2, 1824.

—A manufactory for converting iron into steel has been established in Morris County, N. J. and a for the Philadelphia Democratic Press, says that persuaded no cast steel ever imported from Great n excels it for the firmest and finest instruments.

New Brunswick Fredonian says nothing has yet related to the villains, who robbed Mr. R. nory, but strong hopes are entertained that their has been discovered, and that they will speedily ight to justice.

FOREIGN.

French troops took possession of Barcelona on a Nov. More than three hundred pieces of brass y were mounted on the ramparts. The king of entered Madrid on the 14th Nov. A Paris ar- says that "the people took his horses from his and the king, descending, was drawn into a d Car by 100 men, to his palace under tri- Larches." The Duke D'Angoulême was ex- at Bayonne on his way to Paris on the 25th ber.

London Courier of Nov. 11, states that there ounts from Paris "that vessels of war and pro- were about to be sent to Cadiz, and that trans- carry twenty thousand infantry and two thou- dinary were to be furnished to Spain by differ- of Europe, and to rendezvous at Cadiz. The probability, however, is, that this is but fudge!

—*Greek and Greek Affairs.*—A Constantinople ar- Oct. 10, states that the Captain Pacha had d several Greek vessels near Lemnos. The division consisted of 35 light vessels, and were d with two divisions of the Turkish fleet.— eek account states that Ad. Midoule, with e divisions of fleet, attacked the Turks about the September, near Mytelene;—that the battle e four hours;—that the Grecian fire ships destroy- e large Turkish vessels;—that others were e- ck or stranded on the coast of Asia; that two e captured frigates had arrived at Psara;—and e remainder sought refuge in the port of Olive- e Greek accounts of land operations likewise e their affairs in a favorable point of view. They e at the Turks have been repulsed and harassed e Grecian Commandant Diamante, and suffered e loss;—and that they then retreated towards e, and sustained several sanguinary defeats e route.

16th Sept. the Turkish Pacha Mustapha at- e the Greek General Contavene, who defended e passes leading to Missilonghi; but was re- e with great loss. On the 6th Mustapha attack- e his pass, defended by a corps of Suliots.— e contest was long and bloody, and the Turk e retire from it till he had lost a great number of

icle, dated Zante, Oct. 20, states that in two e Scodians [Turkish auxiliaries] left 2000 e on the field. The loss of the Greeks, who e ended by entrenchments in the passes, was e nty; but among them were three of their e. It appears, however, that Mustapha e afterwards made a third attack on the pass of e was in full march for Missilonghi. But e is strongly fortified. The Citadel of e the same accounts surrendered to the e October. The garrison to be sent to Asia e on is now capitulating. The fort of Rodhy- e surrendered in September; and a Hy- e andron is shortly expected to arrive in the e Patras.

An article dated Semin, (Selavonia) Oct. 20, as- erts as a rumor, that the Greeks have gained a new naval victory over the Turks, the first day of Octo- ber between Lemnos and Mytelene. A Nuremberg article of Oct. 25, states that Arcania is entirely free of the Turks. Privessa and Arta have only small gar- risons, which the Greek Commandant Sturnaris is dis- posed to besiege. Vonizza is in the power of the Greeks. Odysseus is before Nigropont; Colocotroni goes into the Peloponnesus; and Nicetas remains in Livadia. The Pacha of Salonica is repairing to Larissa with some thousand troops, to take the command there.

CONGRESSIONAL.

IN SENATE.—Friday, Dec. 26. Mr. Barton offered for consideration a resolution on the subject of the sale of the *Lead Mines and Salines* of the United States, and of the necessity, if to be sold, of diffusing information among the people of their situation and value.

Mr. Mills, of Mass. gave notice that he should on Monday ask leave to propose an Amendment to the Constitution in relation to the choice of President and Vice President.

Monday, Dec. 29. Mr. Mills, of Mass. introduced a resolution for amending the constitution of the U. S. with regard to the choice of President, &c. and Mr. Van Buren another on the same subject.

The bill to revive and continue the Acts relating to discriminating duties in favor of our commerce was taken up, and debated on by Mr. Smith, Mr. Lloyd of Mass. and others; and finally passed the Senate.

Tuesday, Dec. 30. This day was occupied by at- tending to private bills, and resolutions, which were postponed.

Wednesday, Dec. 31. Numerous private petitions were presented. The bill from the House to repeal part of the Act to lessen the compensation of Marshalls, Attorneys, &c. was read and committed.

On motion of Mr. Elliot, a resolution was agreed to, requesting the President of the U. S. to cause an application to be made to the British Government, thro' our Minister at that Court for a list of names of persons paid, and sums received for Florida lands, previous to the Treaty of 1793, of which they were deprived by the transfer of that territory to Spain, by virtue of said Treaty.

HOUSE.—Tuesday, Dec. 23. Mr. Webster from the Committee on the Judiciary, reported three bills. 1st for the relief of persons imprisoned for debt in Penn. 2d, A bill to repeal in part, the Act to lessen the compensation for Marshalls, Clerks and Attorneys, and a bill allowing costs in all cases, whose patentees recover more than \$100. These bills were committed.

The House took up the resolution of Mr. Breck, calling on the Secretary of the Treasury for the amount of the exports and imports to and from Greece, Asia Minor, and Egypt. This caused some debate in the course of which Mr. Webster said in substance, that the motion he had formerly made was merely to authorize an inquiry into facts as regarded the situation and prospects of the Greeks, and not to produce a quarrel with the Turks, and he wished to prevent any such impression from going abroad as that his resolution was a declaration of war against the Turks.

Friday, Dec. 26. Mr. Sloane, of the Committee of Elections asked for power to send for testimony in the case of the contested election of John Bailey, a Member from Mass., who was stated not to have been at the time of his election an inhabitant of that State, &c. Granted unanimously.

On motion of Mr. Wayne, the Committee on the subject was instructed to report on the expediency of fixing by law the net amount of annual income, which shall disqualify any applicant from being placed on the list of Revolutionary Pensioners.

Tuesday, Dec. 30. Mr. Webster, from the Committee on the Judiciary reported that it is not expedient to establish a Uniform System of Bankruptcy. In this opinion, Mr. Webster observed that a great majority of the committee concurred, and that he was the only member, who had the misfortune to differ from that opinion, but the whole Committee were desirous of giving a fair opportunity to those gentlemen, who like him- self were in favor of the system, to bring the question before the House. *This Report was laid on the Table.*

MASSACHUSETTS LEGISLATURE.

The Legislature of this Commonwealth assembled on the 7th inst. After passing through the customary forms, &c. a joint Committee was appointed, consisting of the Hon. Messrs. Brooks and Austin of the Senate, and Messrs. Hart, Welles and Ware, of the House, to wait on his Excellency the Governor, who soon afterwards transmitted his Message. We would, with pleasure, give this at large, but most, perhaps nearly all, of our readers will receive it from other sources.— The following extract, however, having in part, a particular reference to the objects of this paper, we shall not deny ourselves the privilege of publishing.

"Agriculture, the stable source of the health and strength of the state, encouraged and aided by government, is gradually improving; and with a continuance of the patriotic zeal and exertions of individual citizens, will attain higher degrees of perfection.— manufacturing establishments are extending and increasing, and as the means of protecting them by increasing duties on foreign imports, is, by the constitution, vested exclusively in the federal government, it is confidently hoped, that a review of the existing tariff, an increase of duty on certain articles, and on those particularly which are of primary necessity, may be considered as accordant with, if not required by national policy."

From the National Gazette.

The following beautiful appeal to the charitable, was written by a gentleman in Montreal, when the distress of the poor in that place called loudly on the charity of the opulent, during the hard winter of 1817 and '18.

WINTER.

At this chill time, while stormy winter reigns,
And driven snow lies scattered on the plains;
While bitter tempests howl with furious dread,
And search each crevice of the peasant's shed;
At this bleak home the poor are doomed to know
The cutting pangs of undeserved woe;
To feel the sorrows that from want arise,
While famine waits when craving nature cries.
Bereft of means to earn their food each day
They pine unknown their humble woes away,
Ye sons of fortune, blest with happy lot
Go view the misery of the poor man's cot;
See how distress bows down a father's head,
While hungry infants call aloud for bread;
See the low mother, sickly and opprest,
Weep o'er her child half famish'd at her breast;
Go, view this scene, and teach your hearts to feel
The force, the claim of poverty's appeal.
O! charity, sweet nymph of every grace,
Extend thy arm to cheer a drooping race,
Raise up the wretched from their pining state
And yield thy aid where want and death await.

MISCELLANY.

The following article ridicules with a good deal of humor a propensity of *British* Legislators to over-act their parts, and make laws relating to trifling subjects, which are not required by the wants of society, and whose only tendency is to promote needless and vexatious law suits. The garment was fashioned for the *English* lawgivers, but if it fits any of our *American* Legislative bodies nobody can possibly object to their putting it on.

To the Editor of the Morning Chronicle.

SIR—We have now, thanks to the wisdom of our Legislators, arrived at such a happy pass, that there is scarcely an act of life the due performance of which is not provided for by Act of Parliament. Something, however, still remains to be done; and I am assured by my very good friend, Mr. M——, of G——, that the following Bills are to pass the next Session.

I am, Sir, &c.

TIMOTHY LOVELAW.

An Act to oblige Parents to blow their children's noses, or to cause them to be blown by Nurse, Cook, Housemaid, Groom, Helper, or other proper and fit Person, three times a day in summer, and nine in winter, under the penalty of, &c.

An Act to prevent Adults from swallowing Cherry stones, and giving Magistrates, suspecting the same to be practised, the right of search into private places, Penalties *qua-sent*.

An Act to prevent Cruelty to Flies, Black Beetles, and Fathers Long Legs, with a Clause providing that Moths shall not approach within six inches of any Wax, Mould, Spermaceti, Dip, or other Candle, nor within three inches of any farthing Rushlight.

An Act for better preserving the health of his Majesty's liege Subjects from the dangers too often attending exposure to wetting their feet, whereby many have grievously suffered

coughs, catarrhs, and other maladies, and enacting that persons found walking in wet, damp, sloppy, greasy, splashy, dirty, mucky weather, with shoes, boots, pumps, or slippers, less than three inches thick in the sole from the heel piece to the toe, or four inches in the heel, or with shoes with such a thickness as above recited, but cracked, damaged, burst, worn into holes or otherwise impaired or injured, shall on conviction before a Magistrate or Justice of Peace, be sentenced to the Tread mill for a term not under one month, nor exceeding six, and shall forfeit such shoes to our Lord the King. Persons bare footed, or without shoes, shall be considered as coming under the terms of the act, but shall be exempted from the forfeiture.

An Act regulating the size and weight of penny plum buns, and enacting that not less than six, nor exceeding eight green gooseberries shall be put into a penny tart, on the pain of forfeiture, one half to the Lord our King the other half to the informer. Also a clause for better ordering of lollipop.

An Act to oblige persons to blow cool their hasty pudding in the spoon, for the space of fifteen seconds before eating the same. "For many and divers persons have been grievously burned, scalded, and damaged in their mouths, tongues, gullets, windpipes, and stomachs, by greedily, voraciously, hastily, gluttonously, eating and devouring, bolting and swallowing, hasty pudding, &c. &c. It is therefore hereby enacted, that all grown persons and adults of an estate to hold a spoon, shall blow and puff such hasty pudding in a spoon for a space not under fifteen seconds, under the penalty of, &c."

An Act to prevent parents from eating green Peas with two pronged forks.

An Act to prevent Cruelty to Visitors, prohibiting the galloping of Young children admitted after dinner over the small clothes of Visitors, spilling their wine, eating their fruit, fouling their waistcoats, ruining their neck-cloths, kicking their shirts, calling them names, hawling, squalling, crying, roaring, or singing or spouting at the request of their parents or guardians, to the great detriment of social intercourse and scandal of all good livers; all which things are hereby declared contrary to law, and punishable under the Statute herewith framed and enacted, for preventing the spoiling of children. And be it further enacted, that more than 16 children be never and in no case, permitted or suffered to rush into the dining room when the cloth is removed, but that such irruption shall be a riot, and quelled according to law." The Act goes on to send the parents to the house of correction, for aiding and abetting in such tumults, and further relates the size and shape of pap-boats, and the fashion and figure of corals.

An Act to prevent gluttons from eating worsted stockings, tallow candles, ten penny nails, and case knives, &c. &c.

A singular French Character.—Dr. W. Hutton, formerly of Birmingham, Eng. gives the following account of an English woman. "The greatest wonder I saw in Derbyshire, was Miss Phebe Brown, in person about five feet six, about thirty, well proportioned, round sized and ruddy, a dark penetrating eye, which the moment it fixes upon your face, stamps your char-

acter, and that with precision. Her steps, p dam me for the Irishism, is more manly than man's, and can easily cover forty miles a day. Her common dress is a man's hat, coat, and spencer over it, and men's shoes. I believe is a stranger to breeches. She can lift one hundred weight with each hand, and carry four score. Can sow, knit, cook, and spin, but hate them all and every accompaniment of the male character, except that of modesty. A gentleman of the New Bath, recently treated her so rudely that "she had a good mind to have knocked him down." She positively assumes that she did not know what fear was—never gives any affront, but will offer to fight any man who gives her one—if she has fought perhaps it is owing to the insultor's being a coward, for none else would give an affront. She has strong sense, an excellent judgment, says some smart things, and supports easy freedom in all companies. Her voice more than masculine, it is deep toned; the wit in her favor, she can send it a mile; has heard or prominence of breast; accepts of a kind of manual labor, as holding the plow, driving the team, thatching the ricks, &c. Her chief vocation is horse breaking, at a gallop a week; always rides without a saddle; supposed the best judge of a horse, cow, &c. all the country, and is frequently requested to purchase for others at the neighboring Fairs. She is fond of Milton, Pope, Shakspeare, also music; is self taught; and performs on several musical instruments.

"She is an excellent *markswoman*, and like her brother sportsmen always carries her gun on her shoulder. She eats no beef or pork, and but little mutton; her chief food is mutton and also her drink, discarding wine, ale, & spirits."

Effects of extreme cold.—In the adventure some Russian explorers of high northern fame find the following curious statement;—was now (says the narrator) almost impossible to fall timber, which was as hard as the hardest itself, except it was perfectly dry; and in the greatest severity, the hatchets, on striking wood, broke like glass. Indeed it was impossible to work in the open air, which compelled us to make many holidays much against our inclination. Upon coming out of a warm room it is absolutely necessary to breathe through handkerchief; and you find yourself immediately surrounded by an atmosphere, arising from the breath and the heat of the body, which closes you in a mist, and consists of small particles of hoar ice. Breathing causes a noise like a tearing of coarse paper, or the breaking of thin twigs, and the expired breath is immediately condensed in the fine substance mentioned above. The northern Lights are common and very brilliant; they seem close to you, and you may sometimes hear them shoot along; they assume an amazing diversity of shape, and the Tungoose consider them to be sparks at variance, fighting in the air."

TERMS OF THE FARMER.

Published every Saturday, at THREE Dollars per annum, payable at the end of the year—but who pay within sixty days from the time of subscription will be entitled to a deduction of FIFTY CENTS. No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

NEW ENGLAND FARMER.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

Vol. II.

BOSTON, SATURDAY, JANUARY 17, 1824.

No. 25

tracts from an Address delivered before the Agricultural Society of Susquehanna County, Pennsylvania. By R. H. Roser, Esq.

"The knowledge of agriculture is general, supposed to be simple, and easily to be acquired; and this belief has prevented many from paying that attention to it which is necessary, in order to be well informed in its details. But, besides persevering industry, and diligent care, which are indispensably necessary, science is as important here as in every other place; and no one need hope to become a successful farmer, without a widely extended knowledge of things connected with his art. Placed as we are, in a new country, of much natural fertility, we are not called upon to renovate exhausted, or worn out lands; but all the skill requisite for the farmer who tills those, is equally important to us, in order to prevent the exhaustion of that fertility with which our fields are given to us. Skillful culture can make a poor farm rich; and it must, therefore, be an unreasonable neglect to suffer a rich farm to become poor.

"A farmer should be well informed of the nature of soils, and of the various plants suited to them, in order that he may cultivate them as are best calculated for his particular case, and not waste his labor on those which flourish most in other situations.

"Geologists suppose our earth to have been composed of rock of various kinds, but principally of sand, aluminous, calcareous, and magnesian; and the gradual attrition, decay and mixture of these, together with an addition of vegetable and animal matter, is formed the soil; and this is either sandy, clayey, calcareous, or magnesian, according as the particular primitive matter preponderates in its formation. Sand, lime, and limestone, or calcareous earth, which enters as a manure upon the others, when it exists in too great proportion; in consequence of producing, by their intermixture, an exquisite state of cohesion, not too loose, nor too rigid for the roots of plants; and it is proved by that celebrated agricultural chemist, Mr. Humphrey Davy, that no soil is fertile which contains as much as nineteen parts out of twenty of any of the constituent earths that have been mentioned. Different vegetables flourish best in different modifications of the component parts, as they prefer moist or dry situations; but the most valuable soil for agricultural purposes, is that in which they are found in such proportions, as, while moisture is suffered to pass freely, and roots easily penetrate it, there is sufficient tenacity to give support to the plants, and enable them to spread their leaves and branches to the light and air, and to resist the impulse of the winds.

"Plants resemble animals in many parts of their system. The roots and leaves serve the purposes of a mouth and lungs; and in many instances of their economy, they are not unlike the organization of the nobler parts of the animal. They are operated on by food and drink much in the same way; and, in like manner, as they, in decomposition, an appropriate

food for the vegetable system. Some plants, as the *dionaea muscipula*, the various species of the mimosa, &c. evince an inherent power of motion, and shrink at the slightest touch. The disposition of every tree to throw out its branches towards open places, in order to obtain light and air, and to send off its roots in the most suitable directions in search of food, displays an apparent consciousness of situation.—A tree growing in a position where it is surrounded by others, and defended from the winds, disperses its roots in quest of nutriment near the surface where it is most abundant, and wastes none of its strength in low limbs, but springs upwards, tall and thin. But the same kind of tree, in a situation exposed to the storm, takes firm and deep root in the ground, and, as if conscious of the power of a lever, spreads its branches below, while it contents itself with a moderate height, that the gale may have more readily pass over it.

"It has been much contested, whether earth is of any use to plants, except to afford them a support; water being supposed their chief, and, by some, their only food; but all plants, in some degree, partake of the soil in which they grow; and their ashes, by analysis, are found to contain, besides potash, the carbonates of lime and magnesia, silica, alumina, and certain metallic oxides. It is therefore most probable, that, instead of being the sole food of the plant, as contended by some; or, according to others, the mere solvent of the food, and the means by which the plant is enabled to absorb it, water acts in both ways, as a direct nutriment in itself, and as the means by which the plant is enabled to obtain other food, necessary for its health and vigor. The leaves, as well as the roots, are furnished with absorbent vessels; and some vegetables draw the greater part of their nourishment, by means of their leaves, from the air, which, like the soil they stand in, is a compound, some parts of which are more favorable to vegetation than others.

"The soil of the beech and maple lands, which compose the greater part of Susquehanna county, is a sandy loam, about eighteen inches in depth, resting on a compact bed of argillaceous earth, and minute sand; which, from its retentive nature, is extremely well calculated to prevent the escape of moisture, and to preserve the fertilising quality of the manures which may be intermingled with the superincumbent soil.

"It must be confessed, that agriculture appears to be, in general, but little understood in our county; and the neglect with which fields and farms are treated, is calculated to give to strangers an unfavorable opinion of the soil.—In many places we see fields but lately cleared of their woods, neglected and suffered to be overgrown with bushes and briars; or crop after crop is taken from the same field, the seed having been strewn upon the stubble of the preceding harvest, and merely harrowed in; no plough used; and, indeed, sometimes no harrow, the seed and the harvest being trusted to the mercy of heaven. The soil must naturally

be very prolific, or who could expect to see such a seed time followed by any harvest!

"There is also a want of attention to the fences, as well as of care and of neatness about the farms, for which we can seek an excuse only in the recollection of the very short space of time which has elapsed since every farm, as well as the seat of justice, at which we are now assembled, was covered with an apparently interminable forest. And when we see the improvements which have sprung up with such rapidity, we may reasonably hope, that a few years more will change the inattention which we are now disposed to censure, into economy and care. This Society may do much good; and it is a pleasure to see a disposition to become members of it generally pervade the county. It is to be hoped that reformation will begin among its members. There is no slight connexion between industry and good morals; and we might become more attentive to the appearance of our farms, if we supposed, as is sometimes the case, their condition was indicative of good or ill qualities, as citizens and neighbors, of their owners.

"A farmer should attend to the neatness and convenience of his house, as on that much of the health and comfort of his family depends. The Dutch have a proverb, that paint costs nothing. It preserves and beautifies his buildings; and neatness commenced in one thing, is generally extended to others. But he should remember that his farm is his great object, and take care that no subordinate parts exceed their due proportion of expense. Neatness costs nothing. It is frequently the case that a farmer builds a larger house than he can complete, and it remains afterwards unpainted and unplastered, a mark of his want of skill in proportioning his expenditures.

"No one sees a good garden attached to a farm house, without a favorable opinion of the owner's industry. Much of the attention required in it may be done by children, and much of the comfort and economy of a family depends upon an ample supply of culinary vegetables.

"Great care should be taken in the proper position of the barn, both for the general convenience of the farm, by which much labor may be saved, and for the preservation of the manure made at it, on which much of the farmer's wealth is to depend. The great secret of good farming is, to enlarge the dung heap. Wherever manure can be made in abundance, the farmer has his crops at his command. But when crops are raised, there is no safety for them without good fences. A farmer will be likely to experience more vexation from bad fences, than from any other cause. His own, and his neighbor's cattle are perpetually annoying him; and the fairest hopes of his fields are at the mercy of all the unruly animals on his farm or in the vicinity.

"An orchard is an object of much importance. The best fruits should be planted. The ground they occupy, is the same as that occupied by the worst.

"The indiscriminate destruction of timber,

which we see in this county, is deserving of much reprehension. If, in clearing lands, groves of timber were left interwoven among the fields, besides the beauty of a farm cleared in this manner, they would be useful as a shelter for cattle in the heats of the summer, and as a reservation of fuel, against the time when that article shall become scarce, as it has done in all the long settled counties, where timbered lands are considered much more valuable than the cleared. Many think they can never exhaust the abundance which is around them; but if they will compare what is already cleared off, with the shortness of time which this county has been populated, they will have reason to change this opinion. It has been calculated, that from ten to fifteen acres are necessary for the permanent supply of each fire place, where wood is used much less profusely than with us; and this, independent of all the other farm uses to which it is applied. A farmer should examine his ground well before he cuts a tree, and leave those parts where it will be most useful or ornamental. He should also be careful to leave the best kinds of timber, especially the sugar maple, the produce of which is not only useful in his family, but may be generally sold at twice the expense of procuring it.*—This tree is one of the most beautiful of our forest; and, consequently, if planted along lanes, or division fences, would be ornamental as well as useful.

"No expense should be spared in procuring the most suitable implements of agriculture.—Every one knows the labor which must be expended, and the time lost, if his implements are out of order; and should recollect the adage that "time is money;" an adage, which, I believe, you will all say, is but little attended to among us. A place should be provided to receive all the farming tools, that no time may be spent in searching round the farm for them, when wanted; and whenever an instrument is done with, it should be deposited in its proper place.

"A farmer should not attempt to sow or plant more ground than he can accomplish in suitable season, and attend to in a proper manner. It is better to cultivate one acre well, than several ill. He will get both more reputation and more produce from it.

"The best seeds should always be sown.—Much has been said, and written, about the ne-

* There are some objections against leaving solitary trees standing when woodland is cleared. Trees take root according to their exposure to be shaken by the wind, and their situation as regards soil, sun & air. A tree, growing in a forest, will become taller and its roots will be nearer the surface of the ground, other things equal, than if it grew in cleared land. When its companions are taken away it is very liable to be overturned by wind. We have known instances of very fine "sugar orchards," composed of trees, which were reserved when the rest of the original growth was cut away, turned up by the roots, in a few years; and they generally brought up with them a large quantity of the surface of the soil adhering to their roots. If the soil be stony, very compact, or the trees have always stood in a situation which exposed them to the wind the danger is less. Likewise, if nearly the whole growth is rock maple, it may be preserved, with less liability to the evil alluded to. See N. E. Farmer, vol. i. p. 329, vol. ii. p. 166. Likewise Mr. Rose has himself given reasons why a tree which grew in a forest should not be left alone to bear the fury of the winds. See second column of the preceding page, near the top.—*Editor N. E. Farmer.*

cessity of changing seeds, and procuring new ones from distant places; but doubts may be entertained of the propriety of this practice, especially if a farmer endeavors to raise the best seeds, and if a rotation of crops be attended to. The utility of a rotation of crops appears to be pointed out by nature, in the changes of plants and timber which she is perpetually exhibiting to our eyes. There is every reason to believe, that at a former period this county produced timber different from the kinds which are now prevalent. Places covered with beech, sugar maple, and hemlock, have formerly been clothed with white pine and oak, of which, in some spots, are still to be seen the gigantic remains. And where beech and sugar maple timber have been lately burned off, and the land neglected, other kinds, particularly cherry and birch, in astonishing abundance grow in their places. These are proofs of the changes which nature is constantly effecting.—This disposition to change their ground, has been supposed to be evinced by some plants which are propagated by their roots, as potatoes, which, by extending themselves beneath the surface, form new beds as they spread; and the strawberry effects the same change by its runners. Nature has provided many plants with the power of shifting the position of their progeny, by downy seeds, which are scattered by the winds; others again are furnished with barbs, by which they are attached to passing animals, and carried abroad. Writers on agriculture say, that, by continuing the culture of a particular plant for a long time in one place, the ground, as they term it, becomes sick of it, and refuses to bear it any longer; that is, perhaps, the peculiar quality of the soil, which gave it a strong propensity to a particular vegetation, becomes exhausted, and it is rendered necessary to introduce new plants. But, although this change of plants be proper, it does not follow that a change of seeds is equally so; and I think that farmer acts upon the wisest system, who endeavors to make his own grounds supply him with the best seeds. By doing so, he is more certain of the kind and quality of those which he sows, than when he trusts to those procured from a distance. By crossing different plants of the same genus, it is probable that many useful varieties may be produced.

"The farmers among us who have ploughed their lands, (and foreigners will bear with astonishment of farmers who do not plough,) have found in their crops proofs of the advantage of their culture, but even they do not plough deep enough. The plough cannot be forced to the bottom of our soil—the subsoil is beneath its reach. The quality of the crop must depend, in a great measure, on the depth of ploughing, and the mellowness given to the soil by culture, which enables the roots of plants to spread themselves through it, and obtain more abundant nourishment. Deep ploughing permits all excess of rain to drain from the surface, to a depth where it is retained for the uses of the plants, as their roots may require it; and hence, in such situations, plants are less liable to suffer from the extremes of rain or drought. It cannot be expected that wheat or corn will grow well in ground matted with the roots of grass or weeds. In this particular new land has an advantage over old. It is received pure from the hand of nature; and if weeds are after-

wards seen in it, they are the consequence of neglect. If the proper kinds of grass seed be sowed, in suitable quantity, they will effectually prevent the growth of weeds.

"The grass seeds that are used here, are neither, in general, of the right kinds, nor are they sown in sufficient quantity. Both meadow and pasture should be formed by a mixture of grasses growing at different periods, so that they might follow each other in succession. White clover, among the best pasture grasses, is a native of our soil, and grows spontaneously. Sir John Sinclair, one of the most scientific farmers of the age, recommends land to be laid down with ten pounds of red clover; ten pounds of white clover, ten pounds of trefoil, and three pecks of rye grass seed. He considers the grass better when sown thick; and observes, that if it be sown too thick, it will die off to a proper standard. Some farmers in England sow upwards of three bushels of grass seeds to the acre. Perhaps in our soil nothing would be found superior to a mixture of red clover and orchard grass, both for abundance of produce, and permanency of pasture.

"In England, where farming is carried to great perfection, and where the annual rent and taxes of a farm would purchase the simple of one of the same extent in Susquehanna county, farmers find grass their most profitable produce; and this, although the price of grain, compared with that of cattle, is thirty per cent. beyond what it is with us. Our soil is peculiarly well adapted for raising the artificial grasses; and the distance we are from the markets of Philadelphia and New York, offers strong inducements to the breeding and fattening of cattle. For this purpose, however, our crops are particularly necessary; and to raise these to perfection, manure should be liberally used. We have heard the story of a person removing his barn, rather than his dung heap;—and I am not sure that we could not find examples of this nature in Susquehanna county. In the use of dung, it has been sufficiently proven, that although short and rotten dung will give of some things, the best crop for the first year, yet long dung is more lasting, and will produce a greater effect the second and third years. As Mr. Young, to whom Great Britain is indebted for much of her agricultural knowledge, says, "that sixty-seven cart loads of fresh yard dung produced seven hundred forty two bushels of potatoes; while, at the same time, the same quantity of yard dung, after six months rotting yielded but seven hundred and eight bushels.—but had the fresh dung been kept as long as the other, it would have taken twice or thrice as much to make the quantity used"—the dung rotting settling into a smaller space. A ton of straw, it has been calculated, will, if judiciously managed, make four tons of dung, by which a third of the ground may be manured from which the straw was taken. Dung, during the putrefactive process, gives out gases, which are peculiarly useful to vegetation; and it is most beneficial when applied to the soil during that process. If, as it has been stated, fresh dung is injurious to tap roots, it must be from the excess of its stimulus to the plant. It is considered best not to overload the soil with manure, but to apply it to fallow or root crops only, and that at the rate of from ten to fifteen

per acre. In countries that are very populous, the greatest care is necessary to save every article that will tend to fertilise the ground, in order to supply the demands made on it by the population. The Chinese are said to save from the clippings of their hair and nails for purpose. When their rice fields are flooded, they procure the roe of fish which they put in them, and which vivifying, a part grows large enough to be eaten by the time the water is drawn off, and the remainder, by rotting on the ground, improves its fertility. Young says, "were he an inhabitant of a particular part of France, he would manure four acres annually with flies, which are there in astonishing abundance; and Darwin proposes to place the dung in a situation where it may be flooded with water, and become a moving mass of insect life, in that state to be conveyed to the field." In England, malt dust is not infrequently used; an opulent brewer has even manured his soil with dried yeast. Ground bones are also employed there in such quantities, as to exhaust their own supply, and call for aid from other countries; and not content with the remains of their animals, bits of lace, and fragments of their dresses, sometimes mingled with the imported manures, indicate the search for the means of increasing the product of the farm, to have been added to the cemetery and the field of battle. Among the various things used as manures are, gypsum, chalk, marl, sea shells, common sea and fresh water weeds, fish, hornshavings, woollen rags, ashes, peat, oil cake, soot, &c. &c. Besides clover, buck wheat, and other green crops ploughed in.

A difference of opinion exists, whether the principal quality of dung is lost by being washed in rain below the soil, or by evaporation through it. They who advocate the opinion of the latter, will prefer putting the dung in shallow pits, while others will be in favor of covering it up. Probably both opinions are in some degree, right; and that a part, in the form of gas, escapes into the air, while the more solid part, dissolved by the water, are washed deep into the ground.

Potatoes are an excellent fallow crop; for the prudent of the attention required in their culture, while growing, it is necessary to turn every particle of soil in searching for them at their harvest. Other root crops, however, may be more profitable and their product more abundant. Our soil is extremely well calculated for turnips, ruta baga and man-turtzel, all of which yield great crops. Turnips are usually raised by our farmers for their corn; but although useful that way, I am persuaded that there are few crops which will better pay the farmer's care than turnips raised by themselves. And it is useful for a farmer to have as great a variety of crops and provender, as he conveniently can. Without pumpkins and abundant root crops, he cannot feed his cattle to great disadvantage.

The most approved breeds of animals should be secured, particularly those which are fattened with most ease, as they are kept with less expense than the lank and hungry kinds, and they will repay care and attention to them. The pig-legged hogs costs more to fatten than the pig-legged. The long woolled and valuable breeds of sheep cost no more to keep than those of the worst description; and the cow which

gives an abundance of milk, consumes little more of the farmer's produce, than one totally unfit for the dairy. The most desirable properties of live stock have been treated by writers on the subject, under the heads of size, form, early maturity, hardness of constitution, lightness of oil, prolific quality, a tendency to grow, and a disposition to fatten. It is generally conceded, that moderate sized cattle are to be preferred before the very large ones, as being more easily fattened, kept at less expense, and more marketable. Cattle should be chosen with short legs, their heads and bones small, their bodies long and round, and chests deep and capacious. By an early maturity, much of the expense of their food is saved; which is also the case with those breeds most disposed to fatten.

Every farmer should seek for the best kinds of all the articles which he intends to cultivate; and the county will be greatly indebted to him who shall introduce the best breed of any of the domestic animals, or whose example shall spread among his neighbors the culture of the most useful kinds of grain, grasses and roots.

Domestic Manufactures are intimately connected with the farm. I mean those manufactures properly called domestic—those which are made in the farmer's house and by the hands of his wife and daughters, whom he furnishes with wool and flax of his own produce, and whose industry, properly applied, while it shields them from the dangers of idleness, clothes the family with strong and warm apparel. Too much attention cannot be paid to this, and it remains for the society to encourage female skill and industry, by premiums for the best articles of household manufactures, which shall be exhibited at our next meeting. Of the advantage of these manufactures there cannot be a doubt. They tend to make the farmer independent, by reducing his expenses, and furnishing him from his farm and household with articles of indispensable necessity; and the industry requisite in making them, is useful to the good conduct and morals of his family. But such manufactures are very different in their effect, from those which are accomplished by crowds of men, women, and children, grouped together in buildings which resemble hospitals or barracks, and which must be forced and supported by extravagant bounties, in the shape of duties on importations. The large manufacturing districts in Europe are noted as the abodes of ignorance, want, and disease; and this must be the case wherever thousands depend for their daily bread upon the inclination of one person, or on the uncertain demand for the manufactured article. A diminution of the price of this, may render it impossible for the fabricators of it to procure the means of subsistence; while the situation of the farmer is so fortunate, that no diminution of the value of the products of his farm, can lessen the facility with which he may find the means of support. To him the fluctuations of trade and commerce are comparatively of little importance. The natural and healthy growth of manufactures in the United States, is a desirable circumstance. But great bounties would go to enrich the few owners of the establishments, and be unfelt by the many laborers employed in the works. It was an observation, and a very correct one, of a former President of the United

States, that "Agriculture, Manufactures, Commerce and Navigation, the four pillars of our prosperity, are most thriving when left to individual enterprise." But if, instead of being left to individual enterprise, large bounties are given to encourage the manufacturer, why should not the farmer expect the government to pay him also bounties for his produce, which, when exported, tends to enrich the nation? But the genius of our government is opposed to this system of favoring one class of citizens at the expense of the others; and we had better leave the tangled web of European policy untouched. The conversion of the robust farmer into the pallid manufacturer, certainly does not appear to be a desirable metamorphosis; and the policy of adding to the high duties already laid on imported articles, by which the inducement to smuggling would be increased, and the public revenue probably so diminished, as to lead to the adoption of a direct tax on our farms, is, at least, of a very questionable nature. The certain result of the measure must be, a diminution of commerce, and a serious injury to the prosperity of the navy, which the events of the last war have convinced us, is the cheapest, and most efficient national defence. Is there one so lukewarm as to look with indifference on any source of his country's prosperity and glory! What shall we then think of any measure, which might jeopardize that arm, to which, participating in our country's weal, we look as to the sure guardian of her fame, and the principal foundation of her power!

"If the wealth of a state consists in the surplus of its products, what can be more wise than to promote, by all means, a diffusion of agricultural information among our citizens; and the formation of societies, whose particular objects are the improvement of the soil, and the way to make two blades of grass grow where but one sprung before; or two bushels of wheat where but one could, by the former culture, have been produced? Money appropriated by a government for these purposes, is like a trifling amount of seed scattered on the land, from which an abundant harvest is to be gathered. Frederick of Prussia, who deserves to be not less celebrated as a political economist, than as a successful commander, expended upwards of a million of dollars annually in the agricultural improvement of his kingdom, (one not naturally favored by Ceres) and by this judicious expenditure, he enriched his subjects and filled his treasury to overflowing. Indeed, whatever money may be expended in this way, must be returned to the public coffers infinitely multiplied; and the legislator who acts on different principles, neglects his country's prosperity, and may well be compared to the wicked and slothful servant, who, instead of endeavoring to increase the talent entrusted to his care, concealed it in the ground."

American Salt.—Mr. Van Rensselaer, in his Essay on Salt, states that "In the United States, 1,200,000 bushels are produced annually, and this is a small quantity compared with that which might be had. Yet we import annually upwards of four millions, leaving a balance of more than \$2,800,000 against us. In Illinois, Missouri, Arkansas, Ohio, Virginia, New-York, and Pennsylvania, salt can be produced in the greatest abundance."—*Boston Gazette.*

FOR THE NEW ENGLAND FARMER.

REMARKS ON SEVERAL SUBJECTS RELATING TO RURAL ECONOMY.

[Continued from page 196.]

ON BARN-YARD MANURE.

4. You know Mr. Editor, there are nostrums, besides the metallic poisons, which are recommended as saving remedies for diseases, as different in their nature, as it is possible the human system can be visited with. Yet the *setings forth* of these Empyrics are credited, their preparations purchased, and their directions followed by multitudes, who are wise and careful in many respects—by persons too, who will, not without great trembling, trust themselves to the directions of a physician who, in living among them has recommended himself by his moral and wise conduct. The prescriptions of a wise and discriminating physician are refused, and those patent pills and lotions are bought, taken and recommended as the means of health and comfort; though it is doubtful whether a considerate and well instructed person can be found, who does not suppose the aggregate evil derived from them is manifold greater than the good. But the whole catalogue of the diseases, which the most adventurous of those men have named as cured or helped by their catholicons, will not equal the diversified and contradictory ends, which are expected to be obtained from barn-yard manure: let the land be hill or plain; let the soil be wet or dry; let its constituent parts be clay, sand, gravel or silex; let the crop be corn, beans, wheat or flax; let what will be the changes desired, it matters not; the same nostrum patented, not by Act of Congress but by the law of universal custom, is resorted to, and the same agent is considered as altogether sufficient and operative. The same happy effects are expected, and generally believed to be derived in all cases, however different in their nature. And, if at any time the application fails, the failure is imputed to the moon, or the planetary powers. The disappointed cultivator resolves, instead of changing his application, to pay greater regard in future to the signs of the times. But you, Sir, will not believe the reason why manure does *not* take, is to be found in the silver beams of that lovely light, whose beautiful changes are well calculated to please and delight, but which was never set in the heavens to hurt or destroy. The truth is that barn-yard manure, though of great and extensive use is not good for all soils, nor for all crops; nor in many crops, where it does some good, is it by any means the best and cheapest application that can be made. Applications should be made according to the alterations and changes to be produced. Cold soils want to be warmed, hot soils want to be cooled, hard soils want to be mellowed, open soils to be stiffened—some want heat, some moisture, some, more of both than are afforded by the common gifts of nature. And in all soils regard is to be had to the changes and alterations, which it is wished to produce, and to the wants and habits of the crop to be cultivated. Now can all this be done by one agent? certainly it cannot. But it can be done by a proper application of agents placed within our power, if used in a proper way. To discover these agents and apply them, necessarily requires knowledge and discrimination. A firm then gives employment to the head as well as to the hands; and he only will

be found ultimately to succeed well in the business, who gives his attention to understand the nature of things. The first object to be gained, however, is to convince our agriculturists that the produce of the barn-yard is not, as has already been observed, the only thing, which can make the earth more productive. And that in a very large number of cases it is not the best material which can be applied. And this is a point of a more difficult acquisition than would at first be supposed; or, at least, it is not easy to produce such a kind of conviction as will be followed by a change of practice.

It is not the object of these remarks to descend into particulars relative to the improvement of land. As a general observation the following will hold true. For land very dry, or very wet, pure barn-yard manure is not the best application, which can be made. Common dry, subsoil, and siltious [sandy] earth are better for wet lands.* Meadow earth, and clay are better for sandy and dry land, especially if grass is the crop raised. And I had rather, in many instances that earth should be supplied than an equal quantity of the best manure from the barn-yard. The effect, the first year, in most instances might not be so great; but it would be more lasting, and in all greater. Land between the extremes of wet and dry should be the repository to which the yard must send its treasures. But it must not, if the greatest good is wished to be accomplished, be used alone on grass land. It should be mixed with loam, or covered over after it is spread. The heap should be spread after the grass has started, so that it will soon be shaded. If spread earlier it will often become dry, and lose by evaporation most of its fertilizing qualities. And it sometimes forms a crust, through which the grass cannot penetrate. Compost, brought to a very mellow state is the best for grass. And I am very much of the opinion that clear yard manure should never be used, except when it can be immediately and entirely covered.

FURTHER HINTS ON THE MANAGEMENT OF MANURE.

5. I admire such men as Col. Pickering, who, when they discover any thing useful, have benevolence, and also courage enough to disclose it to the world. Although they may not be the first and only persons, who have thought of such things, they deserve all the honor due to the original discoverers. But such is not the boldness, and therefore not the usefulness of all. Some years before Col. Pickering's publications on the subject of agriculture came to my

* This, however, depends in some measure on the cause of too much moisture. A soil may superabound in sand, and still be too wet for cultivation. "Sandy soils," says Sir John Sinclair, "on a retentive bottom, requires draining." Some swamps, altogether too wet for cultivation, are composed of sand, with perhaps, a slight cover of surface mould. In such case adding sand to sand would produce but little advantage, as respects the superfluous moisture, unless the addition was in such quantity as to elevate the plane of the surface a considerable height above the "retentive bottom" which caused the mischief. And even then the soil will not be valuable in consequence of the predominance of sand. We have known a sharp sand applied to a sandy swamp, to remedy its wetness till a soil was manufactured sufficiently dry but almost entirely barren. If, however, the cause of too much wetness is found in the *absorbent quality* of the soil which induces it to take in water freely, and retain it in too great quantity for the uses of vegetation, sand is a proper application.—Editor N. E. Farmer.

hand, or indeed before he had made any of that subject, I had discovered that the Soo, the Leviathan, that drinketh the rivers, also took away much of the enriching quality of manure used in my garden.—That it was much better to cover green manure in the garden than to suffer it to grow old in the heap; and that crops that covered the ground the greater part of the year impoverish the earth much less than those which were of short continuance.—Yet, such was my deference to the opinions of those, whose business was in the field, and where wealth and substance was drawn therefrom, supposing they must know the better way I hardly ventured to suggest that an alteration from the common practice was necessary. Neither do I believe, I should have thought of giving the public any intimations on the subject.—Yet it is true a change was necessary as the gentleman has told us, and has prevailed on many to their own profit to make; and such, certainly, are the advantages resulting from it that should any man, who cultivates land, pay yearly to this great benefactor a sum equal to his usual town taxes, they, and not he would be the persons obliged.

To the Editor of the New England Farmer,

DEAR SIR,—I am induced to hand you the enclosed extract for publication, from an impression that some of the remarks are so *opposite* to the present juncture, that they ought to be in possession of the public. And this motive I trust, will secure a pardon from my friend for the liberty thus taken.—It may be thought Sir, that the time has arrived for the FARMERS at PLANTERS of the Union, to begin to ask the Government for a share of protection so strenuously demanded by a portion of their fellow citizens engaged in other pursuits.

Should your publication of the letter, meet the eye of the estimable gentleman at the head of the Agricultural Committee of the House of Representatives Congress, he will recognize the writer as one of the most systematic and efficient farmers, upon a very extensive scale, in the United States.

Yours truly,

S. W. POMEROY.

Brighton, Jan. 3, 1824.

* *Genesco, Livingston Co., N. Y. 8th Dec. 1823.*

"DEAR SIR,—I received a few days since, 'New England Farmer.' Judging from the number, I should think it a well selected and judicious paper.

"I doubt whether I should agree with the Editor in recommending the cultivation of roots for cattle. You know my axiom is that the price of farming (I wish I had a better word at command) must be regulated by the price of produce. The same paper which recommends the culture of mangel wortzel, quotes the price of the best pieces of beef at eight cents; reduces the average probably to four cents. I am deceived if it is possible to feed cattle with roots and sell the beef at four or five cents, without loss.—if so, I believe *Say* would pronounce the root culture an unproductive operation. I am not insensible to the fascinating appearance of any section of our country, cultivated nearly the style of horticulture; but its counterpart an afraid even must be pauperism in most of its painful forms. Farmers pursue their interest—not always—but more generally than ye

gentlemen farmers imagine. The nett income of our farmers is miserably small—they cannot afford ornamental husbandry. Labor, says Washington in his letters to Young, is every thing with us, and land nothing. I do not say but you can feed your cows near Boston, cheaper on clover than with hay: I doubt it however.—But can you raise cattle in Ohio and sell them at such prices as will ruin a root-feeder, twenty miles distant from Boston.

Our manufacturers are earning double the amount of farmers of equal capital. Government is paying them a bounty of 30 per cent. on their products—while the good-natured farmer jogs on, quite contented with an occasional burst of splendid declamation in praise of rural life.

I am doubtful as to the expediency of small premiums on cattle; I think the raising of these animals may be left to self interest. Suppose we take a hint from Napoleon, and offer very liberal rewards for great improvements in agricultural implements. The cast-iron ploughs even now cause a saving to the U. S. of at least 0,000 a year—(here is a million saved for other objects.) Our Blacksmiths have lost about a third of their customers' work which was expended in laying and sharpening plough irons.—We have a threshing mill in this village where in use, which operates perfectly well and saves one half the expense of manual threshing, may be transported in a wagon—costs about 0.—We wonder why the Romans did not think of stirrups; and it is a little wonderful that a cast iron plough in its present form has not yet been introduced. There ought to be liberal premiums for great objects that would attract attention through the U. S.—\$10,000 for a flax dressing machine, if it brought one to market, would save half a million a year. Agricultural labor is not up to the lights of the age while mechanical labor since Arkwright began to spin cotton, has been increased many hundred fold. There are many processes in weaving which invite the aid of mechanical inventions; for instance mowing, threshing, cradling, flax-dressing, &c. Mr. Whitney of New-York, made a present to the cotton growing sections of the southern States of a machine, equal in value to the yearly labor of one fourth the black population. I mention it to show what remains to be done, to abridge the rural labor of the northern and middle States.

"I am, &c.

"JAS. WADSWORTH.

"Samuel W. Pomeroy, Esq."

From the Old Colony Memorial.

AGRICULTURAL STATEMENT.

To the Trustees of the Plymouth County Agricultural Society.

Gentlemen,—Having several acres of boggy Fresh Meadow, I have reduced about nine acres of it into good English Meadow. Previous to my commencing any operations on it, it was very ordinary fresh meadow, producing on an average of six or seven hundred of natural fresh hay, of very inferior quality, on an acre, mixed with meadow briars, mountain, and cranberry bushes, near the shores, and on the margin of the reams, bushes of various kinds: all the hay obtained from it would scarce pay the labor of

getting it, and was of more value to put into the barn-yard to make compost-manure, than for fodder.

I began my improvements by clearing out the natural stream, that the water might not overflow, and kill out, or injure the English grass; next laid out the meadow into lands, or beds, two rods wide, from the upland to the brook, digging a ditch three feet wide between the beds. Those beds which were not too miry, I ploughed with one yoke of light cattle, turning the furrows into the middle of the bed, and putting the swamp-mud, &c. taken out of the ditches, into the middle of the beds, to crown them like a turnpike, that the water should not stand on them. I then chopped the whole fine, with sharp hoes, and dug up the whole surface of those beds, which could not be ploughed, with said hoes, and planted the beds principally with potatoes, believing, and afterwards finding it to be necessary to till the ground until I had subdued and killed out the natural grass, &c. The second year I ploughed and dug as before, and planted some of the beds with corn, and some with potatoes; and in some instances I have put a small quantity of barn-yard manure, into the hills. The third year I laid down the beds, by sowing oats, and grass seed, generally a mixture of herd-grass, red-clover and red-top; the oats have generally been very stout, as also the grass which succeeded; and weighing the hay that grew on several of the best beds, the last summer, (being the first time of mowing,) I found them to exceed Four Tons to an acre; I did not weigh them with that accuracy, nor procure the needful evidence, not intending to claim a premium for hay.

I began my operation, on an acre, which lies a considerable distance from the main body, about eight years ago, (as a matter of experiment.) The ditching and digging up of the same cost twelve cents per rod the potatoes on the same, the first year, more than paid all expense, of ditching and digging the same, without any manure.

The second year, I planted thirty three rods of said acre, with corn, and had twelve bushels of good corn, besides small corn, and on the rest of said acre, had 4 hundred and forty six pumpkins, and good potatoes.

Third year, sowed it with oats and grass-seeds.

Fourth year, had a large crop of clover.

Fifth year, 1822, red-top and herd-grass, the whole of which was carefully weighed, and attested to, by an uninterested neighbor, and was three tons and forty four pounds.

Sixth year, 1823, after the hay was well made and ready to put into the barn, I caused to be weighed a number of cocks of hay, which were judged to be an average of the whole, by which it appeared there was on said acre, more than four tons of good hay, principally herd-grass.

In the winter season, between 1821 and 1822, I carted on considerable gravel, and spread it on some of the beds, and am convinced, it had no beneficial effect; I apprehend that the soft mud, at the bottom of the wide ditches, being taken out and spread on the beds, would be a manure far preferable to sand or gravel.

My object in stating particularly, the produce of the first acre, which I cultivated, as a matter of experiment, is to satisfy other farmers, as it has done myself, that English grasses, especially herd-grass, will produce a greater crop, as well

as endure longer, when cultivated on boggy fresh meadow, than an hard upland; and by the mode of improvement above described. Our most unproductive and waste bogs and swamps, may be made, with very little expense, the most productive and valuable mowing lands we have.

Take the whole nine acres, the two first crops, viz. the potatoes and corn have paid all expense of reducing the Fresh to good English Meadow.

JOTHAM JACOB

Hingham, Nov. 17, 1823.

From the New-York Evening Post.

BEES.

A premium was given at our last Agricultural Fair to Mr. Joseph Caywood, of New-Cornwall, Orange county, for some handsome specimens of Honey, which he exhibited, and on the 3d ult. we published a letter from him to the Agricultural Society, in which he gives several interesting particulars as to the improved method of management which he had adopted in relation to his bees, and in particular states that "for the last seven years, I have not intentionally destroyed a single bee." We were desirous at the time, to ascertain how he had contrived to obtain the honey and avoid the usual practice of killing the insects; but this information he declined giving. We now perceive by the *Minerva* of this morning, that the following easy method of taking the honey without destroying the bees, is generally practiced in France:—In the dusk of the evening when the bees are quietly lodged, approach the hive, and turn it gently over. Having steadily placed it in a small pit, previously dug to receive it, with its bottom upwards, cover it with a clean new hive, which has been properly prepared, with a few sticks across the inside of it, and rubbed with aromatic herbs: then having carefully adjusted the mouth of each hive to the other, so that no aperture remain between them take a small stick, and beat gently round the sides of the lower hive for about ten minutes, in which time the bees will leave their cells in the old hive, ascend and adhere to the new one. Then gently lift the upper hive, with all its little tenants and place it on the stand from which the other was taken. This should be done some time in the week preceding Midsummer-day, that the bees may have time, before the summer flowers are faded, to lay in a new stock of honey, which they will not fail to do for their subsistence through the winter.

From the Massachusetts Yeoman.

COAL.

Experiments have been made to ascertain the qualities of the Worcester Coal compared with the Lehigh and Rhode-Island coal; from which it has been ascertained, very satisfactorily, that ours has the superiority over both. A gentleman has handed us memoranda of the experiments made with a peck of each sort, measured with accuracy.—From these it appears that the Worcester coal was wholly ignited in a less time than either of the others, continued burning the longest, produced the greatest degree of heat, and had the least residuum in bulk. The weight, residuum, and time of burning, of the different specimens, were as follows:

	Weight.	Resid.	Time.
	lb. oz.	lb. oz.	h. m.
Lehigh,	18 0	8 14	4 25
R. Island,	18 8	10 06	3 36
Worcester,	22 0	13 00	5 00

It will be noticed that the *weight* of the Worcester Coal, and of its residuum, is the greatest—the measure being the same. This is owing, we suppose, to the iron contained in it.

There can now be little doubt that this Coal may to a great extent supply the place of other fuel. The Lehigh Coal is used at Philadelphia for nearly all the common purposes of fuel, except cooking, and ours is superior to that. We make no pretensions to geological knowledge; but those who do, say that the quantity of our Coal is inexhaustible and widely extended. The pit from which the specimens have been taken, is in the northeast part of the town, not far from Long Pond and has been open many years for the purpose of obtaining *black lead* to be used as a paint.—The Coal may probably be found and easily obtained in other parts of the town nearer the village.

NEW ENGLAND FARMER.

SATURDAY, JANUARY 17, 1824.

ON THE CULTURE OF ROOTS FOR FEEDING CATTLE.

In this day's paper, page 196, we have given some remarks of Mr. Wadsworth, on this subject, in which that gentleman appears to be opposed to this practice. We have not the honor of a personal acquaintance with Mr. Wadsworth but are informed that he is a highly respectable cultivator, who is practically engaged in farming to a very large extent. His opinions are therefore, entitled to the highest respect, and we would by no means venture to oppose our authority to that of an eminent practical as well as scientific agriculturist. All we shall venture to urge in our own behalf is, that if we have gone astray we have not followed blind guides, but have very respectable companions to accompany us in our wanderings. We will produce some of the facts and reasonings which induced us to recommend the culture of roots for feeding cattle, and if insufficient will cheerfully acknowledge our error.

John Prince, Esq., a very respectable practical and scientific agriculturist in the vicinity of Boston, in a communication for the Massachusetts Agricultural Repository of June, 1822, says, "I really wish our farmers, generally, would be prevailed on to raise a greater quantity of vegetables for the use of their stock, than they have been in the habit of doing. Swedish turnips and mangel wurtzel (of the true sort) are very easily raised, and every farmer has land suitable for them, when he might not have suitable soil for carrots, which I think give the richest milk, but are more expensive in cultivation. These roots, with care, even in pits out of doors, may be preserved till May and June, and yield, generally, double the quantity that the same land would yield in potatoes. Indeed with me I have usually had more than three times as many bushels per acre, and with, I think, no more labor. *Mangel wurtzel*, indeed, will, by their thinnings, and trimmings, if done with care, pay all the labor of the crop, and give a fine evening food for cows, and are also excellent food for swine."

Mr. Prince, last season raised a premium crop of mangel wurtzel which consisted of 762 1-2 bushels on an acre and observes "in the same field, and directly alongside, potatoes were cultivated, which fell considerably short of two hundred bushels per acre—the labor in gathering potatoes, is much more than the man-

gel wurtzel; and on the whole cultivation about equal. I think one bushel of potatoes about equal to one and an half of mangel wurtzel for feeding animals. After five or six years cultivation of the mangel wurtzel, I feel convinced it is the most profitable root to cultivate for consumption on a farm, and the past season mine kept perfectly well till June."

Col. John Hare Powel, of Pennsylvania, who is one of the most eminent agriculturists in the United States, and who, we believe, for skill, science and experience, on a large scale in cultivating land has few if any superiors on this side of the Atlantic, in a communication to the Pennsylvania Agricultural Society, at their Meeting held on the 11th of January, 1823, observes, "My neat cattle prefer mangel wurtzel to any roots which I have offered them. I have found its effects in producing large secretions of good milk, very great. I selected in November, two heifers of the same breed, and very nearly of the same age, and in similar condition; they were tied in adjoining stalls, and have been fed regularly three times a day by the same man. One of them has had three pecks of mangel wurtzel, and four quarts of corn meal daily; the other, four and an half pecks of mangel wurtzel. The last which has had mangel wurtzel alone, is in the condition of good beef, the other is not more than what graziers call half fat."

Mr. Powel in another part of the same communication observes, "In citing the experiment on feeding with mangel wurtzel, I have no intention to convey an idea so preposterous as some of the 'Fanciers' have conceived, that mangel wurtzel, or any of the fashionable roots of the day, should interfere with the king of vegetables, Indian corn; or that where land is cheap and labor dear, a farmer is 'wise to amuse himself,' and feed his bullocks by plucking the luxuriant leaves of 'the majestic Beta Alissima.' I would merely recommend its cultivation to a limited extent only, for its influence upon some cattle, milch cows, and more especially upon calves, during the first winter is very important. I have attended with great accuracy, to the ill which are brought upon most young quadrupeds, when first reared; and have invariably found them materially diminished by the use of succulent roots."

It appears by this same communication that Col. Powel raised 222 1-2 bushels of mangel wurtzel on 155 1-2 perches of land. Mr. David Little of Newbury, Mass. raised 970 bushels and one half of a bushel on one acre besides 2 bushels of carrots, and 109 cabbages. Six swine were mostly fed with the thinnings from the beginning of weeding until about the 1st of October.—There are trees on the said lot sufficient to produce 21 barrels of fruit—the entire expense of cultivating this acre of mangel wurtzel, including the cost of the manure and gathering the crop was \$23, 96 c.

Mr. Prince states that his mangel wurtzel weighed about 56 pounds a bushel. And 762 1-2 bushels, at that rate would give 42700 pounds to an acre. This is 19 tons, 16 cwt. and 1 qr.; more than five times the weight which could be expected from grass land of a good quality laid down to herds grass or timothy, the most productive kind of grass usually cultivated in New England. Sir Humphrey Davy in Elements of Agricultural Chemistry, informs that 1000 parts of the white beet contain 136 parts of soluble or nutritive matter. Then, if 1000 lbs. of the white beet afford 136 parts of nutritive matter 42700 (the weight of Mr. P.'s crop) would be 5807 pounds and a fraction over of nutritive matter. An acre of common red clover (*Trifolium Pratense*) producing 49005 lbs. (which is a large

crop) contains according to the chemical analysis, 1914 lbs. of nutritive matter. Thus it appears that one acre of mangel wurtzel may produce more nutritive matter than three acres of stout clover. I might proceed further with our calculations of this sort and show the advantage of raising turnips and rutabaga for feeding cattle, as a second crop, according to methods practiced by Mr. Bucl, detailed in the New England Farmer, vol. ii. page 177, but have not at present room or leisure to pursue this subject.

Mr. Wadsworth asserts that he "can raise cattle in Ohio, and sell them at such prices as will ruin a root-er or twenty miles from Boston." This, however, cannot well be done unless his cattle fatted in Ohio were driven for sale to Boston market. And when that gentleman takes into his calculation the loss of flesh which his cattle would undergo in so long a journey, the expense of their driving, and keeping on the road, we are inclined to think he will doubt his ability to ruin root-feeder by the means he mentions. Mr. Wadsworth adverts to the low price of beef as an argument against root-feeding. But if cattle can be fattened cheaper roots than on other feed the low price of beef presents an argument in favor of root-culture.

LIST OF AGRICULTURAL BOOKS, FOR SALE BY THE PRINCIPAL BOOKSELLERS IN BOSTON.

- A Treatise on a New System of Agriculture, and feeding of Stock.* By GEORGE ADAMS. Wells & Lilly, 93, Court Street.
- A Year's Residence in the United States of America in three parts.* By WILLIAM COBBETT. Wells & Lilly.
- Agricola*, Letters of, on the Principles of Vegetation and Tillage, written for Nova Scotia. By JOSEPH WELLS & LILLY; Cummings, Hillard, & Co., Cornhill.
- American Gardener*, exhibiting the time for every kind of work. By an OLD GARDENER. Richardson & Lord, 75, Cornhill.
- American Gardener*, a Treatise on the Situation of Fencing and Laying out of Gardens, &c. By WILLIAM COBBETT. R. P. & C. Williams, Cornhill Square.
- Arator*, a Series of Agricultural Essays, Practical & Political. By JOHN TAYLOR. R. P. & C. Williams, Charles Ewer, 61, Cornhill.
- Butler's Farmer's Manual*, being a plain, practical Treatise on the Art of Husbandry, &c. Wells & Lilly, Samuel T. Armstrong, Charles Ewer.
- Code of Agriculture.* By SIR JOHN SINCLAIR, & Co. & Lilly; S. T. Armstrong; Cummings, Hillard, & Co.
- Compendium of Cattle Medicine*, or Practical Observations on the Diseases of Cattle and other domestic Animals, except the Horse, with a series of Essays on the Structure, Economy, and Diseases of Horned Cattle and Sheep. By JAMES WHITE, &c.—Richardson & Lord; Wells & Lilly.
- Complete Grazier*, or Farmers' and Cattle Breeder's Assistant, comprising instructions for buying breeding, rearing and fattening of Cattle; Directions: the choice of the best Breeds of live stock; the Treatment of their Diseases, and the Management of Cows and Ewes during the critical times of calving and yearning. The general Economy of a Grass Farm.—Irrigation or Watering of Meadows; Culture of the best natural and artificial Grasses, and Plants for fodder; various Methods of cutting, mixing and preparing food in severe winters, and seasons of scarcity the Economy and general Management of the Dairy including the making, curing and Preservation of Butter and Cheese, &c. &c. Together with an Introductory View of the different Breeds of neat Cattle, Sheep, Horses, Asses, Mules, Poultry, Rabbits, &c. Farm Accounts—and on the Improvement of British Wool. By a LINCOLNSHIRE GRAZIER, assisted by Communications from several Yorkshire, Leicester and Norfolk Farmers. R. P. & C. Williams.
- Cowley's Observations on Live Stock*, &c.—Wells & Lilly.

[Remainder in our next.]

* See New England Farmer, vol. ii. page 171.

† See New England Farmer, vol. i. page 179.

The quantity of flannels manufactured within 40 miles of Boston, the last year has exceeded fifteen thousand pieces of 46 yards each; comprising the various quantities and colors usually imported—and the new establishments now going into operation, with the extension of those already in operation, will manufacture more than thirty thousand pieces the present year.—Besides these, there are others in Connecticut and New York, of considerable extent, and all of them will be sufficient within 18 months to supply the wants of the country, of this comfortable and health preserving commodity.—*Boston Centinel*.

Cheese.—In the township of Aurora, Portage county, there has been made, during the past season, one hundred and twenty-five thousand pounds of cheese, for an area of five miles square, in a new country, in connexion with the ordinary productions of well cultivated farms, is an example of industry and economy worthy of imitation.

Caution.—A child was lately poisoned in Pennsylvania, by its mother's administering the herb called Bear's foot, as an antidote for worms.

FOREIGN.

The English Parliament was to have met in January, but has since been prorogued to the 23rd of February, which delay is considered to be an indication of continued peace.

The last London dates are to the 29th Nov. The press affirm that the French Government had disavowed any intention of assisting Spain in recovering her South American Colonies. It appears, however, that the King of Spain is dedicating a part of his *imperial* labors to the affairs of his Colonies; and the *Spanish* Ambassador to Spain has intimated that his master is willing to assist him in recovering his power his "numerous kingdoms," including "his dominions in both Worlds."

The London papers also assert that Ferdinand and French Prince have quarrelled, and were at dead-pan, and that the latter had left the kingdom in flight. But probably this news was manufactured in London, for the use of the printers. There is every reason to believe that Spain will settle down quietly under despotism, and their Monarch remain firmly seated on a throne supported by servility and superstition, the pillars of all absolute governments.

CONGRESSIONAL.

House.—Tuesday, Dec. 30. Mr. Rich offered a resolution, which was adopted, for taking measures to prevent hunting and trapping on lands to which the Indian title has not been extinguished, and exclude foreigners from the participation in the Indian trade.

Wednesday, Dec. 31. The bill from the Senate on subject of discriminating duties was passed and sent to the Senate.

The President transmitted a Report of the Secretary of State relating to the condition and future prospects of the Greeks. This consisted of various papers, the substance of which alone have been published.

Senate.—Friday, Jan. 2. Mr. Hayne presented a resolution of the Legislature of South Carolina, expressing their sympathy in the cause of the Greeks, &c. which was laid on the table. The principal part of the message of the day was of a private or local nature.

Tuesday, Jan. 5. Mr. Lloyd of Mass. submitted a resolution for opening a communication between Buzzards Bay and Barnstable Bay, through the isthmus which separates those Bays, which after the completion of the Chesapeake and Delaware and Raritan Canals, would extend an inland water communication to the Albemarle Sound to Massachusetts Bay, passing its progress through the territory or along the borders of ten of the Atlantic States.

Wednesday, Jan. 7. Mr. Barbour submitted a resolution, requesting the President to furnish information respecting the relations between Spain and the United States, &c.

The Senate, in Committee, resumed the consideration of the bill allowing the sum of \$23,700 and interest thereon, to the grandson of the late Col. John Lauriat, for services rendered by the deceased, during our revolutionary war, which was originally introduced by

Mr. Barbour. This caused considerable debate, principally on the question of allowing interest on that sum. The bill was ordered to lie on the table.

House.—Friday, Jan. 2. A list of Balances due by individuals to the Government was presented, and ordered to be printed.

Mr. Brock's resolution calling for specific information on the subject of the commerce between the United States, and the countries under the Turkish Government, &c. was adopted.

Mr. Webster's motion for sending an Agent to Greece, was postponed for the purpose of receiving further information on the subject, called for on the motion of Mr. Mallory of Vermont.

Jan. 5 and 6. The House was mostly occupied on Bills for the relief of individuals and Reports on petitions.

Wednesday, Jan. 7. A Report of the Secretary of War, respecting certain contracts for cannon, on motion of Mr. Cooke was referred to a Select Committee.

This day was chiefly occupied in a debate relative to a contested election from the 30th District of the State of New-York between Isaac Wilson and Farnie Adams. The question was whether a printed ballot, having the stroke of a pen drawn through it, should or should not be admitted as a valid vote. The printed letters were distinctly legible, but a dash with a pen was drawn across the whole name; on this account the inspectors rejected the vote and it was not counted. The omission of this ballot, after the deduction on each side for erroneous returns, gave Mr. Adams a majority of one. The House decided that this vote ought to be omitted, and that Mr. Adams was entitled to a seat. Ayes 116, Nays 65.

MASSACHUSETTS LEGISLATURE.

SENATE.—Thursday, Jan. 8. The different parts of the Governor's Message were referred to Committees according to the usage in such cases.

Friday, Jan. 9. The Hon. Messrs. Mills, Hull, and Hubbard were appointed a Committee to report on the expediency of repealing the acts of June 17, 1809, for establishing the Governor's Salary.

Saturday, Jan. 10. A bill respecting "Public Worship and Religious Freedom" was read, 300 copies ordered to be printed, and Tuesday next assigned for a second reading.

Monday, Jan. 12. A Joint Committee, consisting of the Hon. Messrs. Thaxter and Mills, Messrs. Miller, Warren, and Curtis was appointed to report on the expediency of amending the laws respecting paupers.

Resolutions from Tennessee respecting a Congressional Caucus, were committed to the Hon. Messrs. Leland, Winthrop, Freeman, S. Willard and Barker.

Resolutions from Illinois, respecting the appropriation of lands for purposes of education to Hon. Messrs. Gorham, Richardson, Swett, Johnson and Sprague.

Tuesday, Jan. 13. The Hon. Messrs. Adams and Lummus were joined to the Committee to consider the expediency of requiring officers making attachment of Real Estate on mesne process, to leave notice of such attachment with the Town Clerk of the town, in which the land so attached may be located.

House.—Thursday, Jan. 9. The Committee on Turnpikes was directed to Report on the expediency of encouraging the use of Broad Wheels. Other business of a private and local nature was transacted.

Friday, Jan. 9. The Speaker laid before the House a letter from Alden Bradford, Esq. accompanied with a volume of the Massachusetts State Papers, and a volume of the History of Massachusetts presented by that gentleman, to be placed among the public documents of the House. The Speaker was requested to present the thanks of the House for the donation.

The petition of J. H. Coffin and others, in behalf of the Massachusetts Medical Society, praying that means may be taken to prevent the sale of medicines except by persons licensed by the society, &c. with remonstrances, &c. was called up and committed.

The Committee appointed at the last session to enquire into the state of the Gaols in Middlesex county, made a Report, which was read, and ordered to lie on the table.

Saturday, Jan. 13. The Secretary presented a Message from His Excellency, referring to the statement made by the Directors of the State's Prison, re-

lative to the labor performed by the convicts for the use of the General Hospital. Also a Message, referring to certain resolutions of the Legislatures of Illinois and Tennessee.

A Committee was renewed to Report on the expediency of amending or repealing the law respecting *Impounding of Cattle*.

Messrs. Gardner, Putnam, and Tower were appointed a Committee on the subject of taxing Manufacturing Companies.

Monday and Tuesday, Jan. 12 and 13. The proceedings of these days were of a local and private nature, and nothing of general interest was finally disposed of.

FARMER WANTED.

WANTED a married man to carry on a Farm of about 40 acres, within about five miles of the city, and in an excellent neighborhood. This farm is of an easy cultivation, and will be principally appropriated to grass.—A person will receive good encouragement, and may make an arrangement for a number of years by applying to this Office.

FARMER'S ALMANAC, FOR 1824.
FOR sale at this Office, the Farmer's Almanac for 1824. Nov. 24.

INTEMPERANCE.

Most men, too passive, when the blood runs low,
Too weakly indolent to strive with pain,
And bravely, by resisting, conquer fate.
Try Circe's arts, and in the tempting bowl
Of poison'd nectar, sweet oblivion drink.
Struck by the powerful charm, the gloom dissolves
In empty air, Elysium opens round.

A pleasing phrenzy buoys the brighten'd soul,
And sanguine hopes dispel your flitting care;
And what was difficult and what was dire,
Yields to your prowess and superior stars:
The happiest you of all that e'er was mad,
Or arc or shall be, could this folly last;
But soon your heaven is gone; a heavier gloom
Shuts o'er your head: and, as the thundering stream,
Sworn o'er its banks with sudden mountain rain,
Sinks from its tumult to a silent brook;
So, when the frantic raptures in your breast
Subside, you languish into mortal man:
You sleep, on waking find yourself undone.
For prodigal of life, in one rash night
You lavish'd more than might support three days.
A heavy morning comes; your ears return
With ten fold rage. An anxious stomach well
May be endur'd; so may the throbbing heart:
But such a dim delirium, such a dream
Involves you; such a dastardly despair
Unmans your soul.

Besides, it wounds you sore to recollect
What follies in your loose unguarded hour
Escaped. For one irrevocable word,
Perhaps that meant no harm you lose a friend:
Or in the rage of wine your hasty hand
Performs a deed to haunt you to your grave.
Add that your means, your health, your parts decay;
Your friends abandon you; brutally transform'd
They hardly know you:
Despis'd, unwept, you fall; who might have left
A name still to be utter'd with a sigh.

MISCELLANY.

From the Portsmouth Journal.

LOVEWELL'S FIGHT.

The authenticity of historical facts of ancient times rests often upon tradition only. It is believed that Dr. Belknap, in his History of New-Hampshire, was in one instance misled by the information he received. He has laid the scene of an action of a century ago, in the town of Wakefield, which it is apprehended actually occurred on the shore of Winnepesaukee Lake, and probably near Alton Bay. I refer to the achievement of Capt. Lovewell, so renowned in the early wars of this country, as an Indian Partisan. In the winter of 1725 Capt. Lovewell, with a party of men, undertook an expedition into the part of N. Hampshire now constituting the county of Strafford, and succeeded in destroying a company of ten Indians who were directing their course to Dover. The historian of New-Hampshire has stated this occurrence to have been at the head of the western branch of Salmon Falls river, in the town of Wakefield. The pond there has always retained the name of Lovewell's pond. The statement which follows is from the journal of an intelligent and enterprising young man, who was afterwards extensively known and respected.—I mean the late John Varnum, Esq. of Dracut

"John Varnum, when twenty one years of age, went with Capt. Lovewell after Indians in the winter of 1725, on snow shoes, and carried their provision on their backs and travelled towards Winnepesaukee pond and came on the trail of Indians which they followed, till they came to the aforementioned pond. There not being any snow on the pond, they could not see their tracks. There appeared a large flock of ravens, which followed the Indians, lighting on the trees that were on the islands in said pond: which was considered by the Captain and others as ominous of their destroying said Indians. After following the ravens, sometime, they came in hearing of the Indians firing at heaven and other game;—they had a great hunt that day. Lovewell and his men halted sleeping the Indians would eat heartily, and sleep sound. They therefore concluded to come upon them about the middle of the night.—They did not build any fire, but came so near as to see their fire. They tied the mouths of their dogs, and kept them close for fear of being discovered. On the 20th of February they came up and fired on them; and killed eight, and wounded one. One man and the dogs caught him. They were all killed, being nine men and a boy. The boy was armed with a lance on a pole: supposed to drive and torment prisoners. After scalping the Indians, they left them for the ravens.—The Indians were going to Coheco.[now Dover,] to destroy a few settlers there.—Lovewell and his men marched to Dover, it being the next settlement, and from thence to Andover." P.

Wakefield, January, 1824.

Morbid Affection.—The possibility of contracting intemperance from a dead subject is amply confirmed by the following melancholy circumstance. About a fortnight since, Mr. H. Penefather who had just commenced the practice of surgery, was engaged in dissecting the body of a female subject, whose death was produced by inflammation of the liver, attended with other symptoms that rendered the cure worthy of very strict examination. Dissection was submitted to by the friends of the deceased: and Mr. Penefather and another gentleman operated twice or three times with great professional advantage.

The body was interred, and Mr. Penefather thought nothing more of the circumstance until about a week after, when he perceived that his left hand began to swell, a little above the palm, or near the articulation of the wrist, attended with a slight twitching pain and numbness of the fingers. Those symptoms he attributed to various causes, and conceived that the swelling would abate by washing the part with a suitable lotion. This remedy he accordingly tried when retiring to bed; but to his great surprise and no small consternation, he found that the inflammation had extended itself to the arm, which on the following morning was exceedingly swelled. Under these circumstances he deemed it advisable to state the case to some of the more experienced of the faculty; and, after mature deliberation by three eminent practitioners, with reference to his late anatomical researches, (as before stated) they concluded that he must have imbibed through some medium, whether by a cut or otherwise, a portion of the poisonous matter with which the morbid subject was at that time infected. Mortification being seat-

ed in the arm, we regret to learn that he was compelled to submit to amputation, as the only means by which life could possibly be preserved. Mr. Penefather is a native of Ireland, and very respectably connected in that country. [London paper]

Mankind Classed.—Mankind, may be divided into three classes.—Those who learn from the experience of others—They are happy men.—Those who learn from their own experience.—They are wise men.—And, lastly, those who learn neither from their own nor from other people's experience.—They are fools.

Idleness.—There is no character in society more despicable than the idler. He is not only an unhappy, but in a fair way to become a criminal being. Bishop Taylor observed lately, who neglected the education of her son on the plea that he was too young to be committed to study, "Madam if you don't fill his mind with something, believe me the devil will."

Life.—Life is time well employed. A man, therefore, who squanders away his time, commits a species of suicide; and he who wastes more of my time takes away my existence, is more my enemy than the person who justly takes away my money.

The proper Employment of Ridicule.—There are some vices which ought to inspire us with detestation, and others which are most successfully encountered with ridicule. Of this last class are most which originate in an inordinate desire of appearing fashionable and genteel, such as coquetry and foppery. Convince quettes and fops that the world laughs and despises them, and you will do much to reform them.

False Pleasure.—Some men, in pursuing pleasure, destroy their senses, which are only inlets to the enjoyments they are seeking. They roar bacchanalian songs till hoarse deaf, smoke till blind, and drink till stupid.

"In wild excess the vulgar breast takes fire,
Till buried in debauch the bliss expires."

A man should neither choose to be a hero nor a buffoon; human nature is not so miserable as that we should be always melancholy nor so happy that we should be always merry.

The triumph of woman lies not in the adoration of her lover, but in the respect of her husband, and it can only be gained by a constant cultivation of those qualities which she knows he most values.

The supercilious, however refined are rare.

Irish Humor.—An Irishman seeing an out passenger of an English stage coach covered with dust, observed, that if he was a potato he might grow without any further planting.

TERMS OF THE FARMER.

Published every Saturday, at THREE DOLLARS per annum, payable at the end of the year—but if you pay within sixty days from the time of subscription it will be entitled to a deduction of FIFTY CENTS.

No paper will be discontinued (unless at the discretion of the publisher,) until arrearages are paid.

NEW ENGLAND FARMER.

PUBLISHED BY WILLIAM NICHOLS, ROGERS' BUILDINGS, CONGRESS STREET, (FOURTH DOOR FROM STATE STREET.)

Vol. II.

BOSTON, SATURDAY, JANUARY 21, 1824.

No. 26.

acts and Observations relating to Agriculture and Domestic Economy.

[BY THE EDITOR.]

ON THE USE OF SALT AS A MANURE.

[Continued from page 180.]

The pamphlet of Mr. Hollinshead adverted to our last observations on this subject states that for meadow [mowing] land we should advise a farmer to sow six bushels of salt per acre, immediately after the hay is got in. This could be found peculiarly beneficial in hot and dry summers, and upon limestone and sandy soils; which, after they are mown are often so parched by the heat of the sun, that not only the eddish [rowen or aftermath] is destroyed, but also the crop of the succeeding year is materially injured; but by sowing it with it, moisture would be attracted and retained, sufficient to assist vegetation so powerfully, as a short time again to cover the face of the ground with grass, and by that means effectual to screen the roots, which would otherwise be too much exposed to the direct rays of the sun.

"It may indeed be said that dung will answer the same purpose: in some degree it might, but dung cannot always be had, never in sufficient quantities; besides, if it could, this objection is against it, that neat cattle will not eat the fish [rowen] after dung, consequently one valuable crop is lost to the farmer, which if salt were used would be both productive and wholesome."

Mr. Beck, gardener in Chorley, has constantly made use of salt in his garden for upwards of twenty years, principally upon his onions; and has invariably found the salt to exceed every other kind of manure, which he could have used for the like purpose; his method is to sow salt immediately after the seed is covered.

But as he never had any thoughts of communicating the result of his observations and experiments to the public, he took no care to ascertain the exact quantity necessary to be sown per acre, and proportionably upon any smaller quantity of ground; yet he thinks, if he might make a conjecture that he has not sown less, probably more than sixteen bushels per acre. Year by year he sowed the usual quantity of salt upon a plat of onions, after they began to show themselves above ground, the crop, so far from being improved was really spoiled; from this he infers that the experimental gardener, who may be inclined to the use of salt, will do well to throw it on as fast as possible after the seed is sown."

The remarks in the three following paragraphs as well to other improvements in husbandry as to those which may be made by salt. I know some will say that there are many things which cannot be improved. I deny the assertion. Let but the farmer be properly encouraged to make the trial, and I am convinced he will not find his labor lost. If our ancestors were always been indifferent to agricultural improvements, what must have been our situation at the present day? We might have lived on haws and berries of the field; for nature has

not been so lavish in her gifts to this country as to some others: few of the necessities of life will thrive and flourish without the most unremitting industry. *By nature our apples are crabs, and our plums sloes!* but art and nature have changed the scene: and health giving exercise, properly directed, and duly encouraged, would bring the kingdom to an unexampled pitch of plenty and splendor.

"The proper cultivation of the soil is an object so peculiarly interesting to the community at large, that those who industriously attend to it are perhaps to be esteemed the most meritorious citizens of their country."

"Of such importance are the study and practice of agriculture in Scotland, that they have instituted a professorship in one of their universities; and it is much to be lamented that a similar institution is not introduced into our universities, as it would essentially tend to the promotion of the most important department of knowledge, so highly beneficial to mankind."

"A farmer at Glasson, near Lancaster, has for some time been in the habit of carting salt water to put upon his dung whilst in the heap in the yard, before it was taken to be spread upon the ground, which he has found by experience very much enriches the dung, and makes it better manure. A great advantage might also be derived to the farmer from spreading sea-sand under and amongst the dung, whilst it is in collecting during the winter, and also in the cow-house stable, not only on account of the particles of salt contained in it, but likewise by its retaining and absorbing the urine of the cattle, which is itself a very excellent manure."

"Salt is the mother of manures, as every kind is higher or lower in value according to the salt it produces; and every kind of manure is portioned out to the land according to the quantity of salt or nitre it is thought to have in it. Formerly salt was thought to be an impoverisher of land, but experience has taught us wisdom; it is now found to be otherwise, provided it is duly proportioned to the state the land is in, and mixed to mollify it as follows: take ten bushels of salt, and six bushels of dry ashes, and mix altogether; then spread them on the land, and barrow them in with the seed: this is a sufficient dressing for an English acre, as it is better to repeat the dressing than to lay too much on at once. By being thus mixed the particles incorporate with and mollify each other. Salt itself is rather too severe and harsh in its nature, and if laid too thick on, might prove of bad consequence; but if conveyed into the earth by a soapy smooth method, will prove the real enricher the earth wants to send forth vegetation; this dressing will last for three crops."

--From C. Varley, Esq. communicated to the *Chester Chronicle* by the Rev. B. Daere of Mosely, near Manchester.

The following is said to be from the pen of the Right Honorable Lord Erskine.

"The science of agriculture is by no means at its height; and in the almost miraculous advance of chemistry new means may be found from the concentration of known composts and the discovery of new, to lessen the costs of cul-

ture and increase its returns. But here again your revenue stalks like a ghost across my path which ever way I turn; as otherwise you have a superior unbounded source of improvement trodden under your very feet, and cast as refuse into your rivers, beyond all that chemistry is ever likely to discover. You have salt in endless abundance. But your necessity turns it into money, even to forty times its value, instead of spreading it abroad for various uses to rise up in property, which no money could purchase."

"Do you know what salt alone would do for you? Can you be so ignorant as not to know, that by taking the tax upon it directly as money, you rob yourselves of fifty times its amount in the productions of your soil, in your fisheries and manufactures, and in the universal prosperity of the country?"

"Lime, which has caused to start into life the most inert and sterile parts of Great Britain, is just nothing as a manure when compared with salt, which differs from it besides in two remarkable qualities, decisive of its superior value."

"Lime, and I believe all other known composts, are powerful only according to the quantities in which they are used; whereas salt to be useful must be sparingly applied; it corrupts vegetable substances when mixed with them in small quantities, but preserves them, when it predominates in a mass. It is needless therefore to add, that independently of its comparative lightness, the expense both as to the article and its carriage must be greatly diminished. Yet you rob the mother of our people of this food which indulgent nature has cast into her lap, sufficient as you will see hereafter, to feed all her children, even if their numbers were doubled."

Another English writer informs that "Salt answers best as a manure for green crops, especially for turnips and clover. It is not of much benefit to barley or wheat, if sown; but in compost it proves very advantageous using thirty Cornish or forty-five Winchester bushels per Cornish acre, which is larger than the Statute acre nearly in the ratio of six to five. Prepare the ground for turnips, and sow the salt a fortnight before the seed, or longer if a larger quantity of salt is used."

"Mr. Seckler, at Haver, in the parish of Gwinear, has just applied salt in the above proportion to poor exhausted land; being clay, inimical to turnips: the effect has been a heavy, rich crop, which I have had an opportunity of seeing. It is such a one as a hundred tons of dung per acre would scarcely produce in the same land. The salt employed is that which is considered refuse after having cured the fish, and been condemned by the excise. Over this they throw some dirt, and it is then sold to the farmers by the fish curers. If the duty were taken off salt, for every bushel now used, there would be at least a hundred bushels employed for this purpose. It has been said that the value of refuse salt, as manure, depends upon the soil and animal matter which adheres to it; but the farmer knows from experience, that salt is to be preferred which has cured only one bulk of fish; and they give a higher price for it than for that

which has been twice employed, and which consequently contains more animal matter. Where an estate has been salted for two or three crops, the effects are visible for at least seven years. It has a particular tendency to convert poor and light soils into firm and adhesive ones, 'giving them body.' Among the farmers there is a general scramble for the refuse salt, to try who can get most of it by purchase.

"The following curious anecdote may be related as serving to illustrate the effect of salt: Mr. Seckler made a little heap of earth in the midst of a field, on the top of which a cart load of refuse salt was thrown; the earth in the heap itself, and (after its removal) the earth under it, for upwards of two feet deep to the clay, was rendered so perfectly barren, that the most common weeds would not vegetate in it. This barren earth, however, furnished the richest dressing for the remainder of the field. Mr. Seckler found salt the best preservative against mildew in wheat. When the wheat followed turnips with salt, it escaped the mildew which attacked other fields which were not salted; and this he finds to hold universally good, as far as his experience goes. The improvement of bad hay, by salt applied in the proportion of about one hundred weight* to three tons, and sprinkled between the layers, is very striking, preventing mildew, and rendering it more grateful and beneficial to cattle, especially if the hay is bad; and even in good hay it is very greatly ameliorated. A testimony in favor of the benefit of salt is furnished by the striking fertility of the land in the neighborhood of the sea-shore in Cornwall; more especially in those situations which are favorable to the general distribution of the saline spray, as is exemplified in the parish of Fenno."—Sir Thomas Bernard's *Case of the Salt Duties*, page 272, communicated by Dr. Paris, late of Penzance, but now of Dover Street, London.

* This is foul fishery salt; of pure salt, a third of the quantity might be sufficient.

(To be continued.)

Extracts from an Address to the Hampshire, Franklin and Hampden Agricultural Society, Northampton, Mass. October 23, 1823. By ISAAC C. BATES, Esq.

"It is too late, I apprehend, to arraign the policy or question the propriety of our agricultural associations. If there be any thing worthy of patronage, it is the art upon which all other arts depend; the occupation, without which all other occupations are useless.

"The Dublin society, established in 1731, as it was the first in order of time, so it was for a series of years supported by the voluntary contributions of its members, until at length, its effects becoming apparent, other societies were formed; and now they are established throughout Great Britain, France and Germany, and indeed throughout Europe. All that is granted by this Commonwealth, and the several states combined, for the encouragement of agriculture, is absolutely nothing compared with what is done by France for a single national establishment, and that too in a land of vines and olives. Experience, therefore, has settled this question; experience in different countries; under great diversity of forms. It is not too

much to say, we have the judgment of mankind in our favor; not upon a subject remote from observation and difficult of research, but full in the public eye opened by its effects and known by its fruits. What then ought the conjectural scruple of the prospective calculator to avail, against this mass of practical evidence, which near a century has accumulated? If the only effect of our act of incorporation were to bring together once a year, the gentlemen whom I now have the honor to address; awakening their attention to what has been done and what is doing; leading them to an interchange of views and feelings; animating them to enterprise and emulation; I should think the society rested upon an unquestionable basis of utility.

"Let it not be imagined, gentlemen, there is nothing more to be learned in the arts of life. No obstacle to the march of mind, is more insurmountable than the conceit, that we are wise enough. It closes the eye of enquiry and shuts out the light of knowledge. True, according to the received chronology, this world is about six thousand years old. Yet it was more than four thousand years before you learned how to make a good plough. Cincinnati talked with as much complacency as we do of "the good old way," when he was following his land with the limb of a tree for his plough beam and a knot to it for his coulter and share; and the patriarchs, when they were grinding corn with pestles. How long since you learned the art of printing—and a thousand other arts? How long since you found out the value of the potatoe? Since you naturalized Dutch clover? Since you discovered that your plain lands were not made in vain? Depend upon it, gentlemen, there is a better way than that now in use, in every act of field husbandry, and in every operation of mechanics. Think you, that in this immense repository in which we live, you have explored the whole of its contents—or any part of them? The recent discoveries and improvements in the arts and sciences shew, that even now, in this age of late and fancied maturity, knowledge is in its pupilage. I would excite you, therefore, to a thinking cultivation of your lands; to attentive and nice observation. Push your inquiries to the extent of your capacity, and your experiments as far as a prudent economy will permit; and make no other use of "the good old way," which is often circuitous and often bad, than to keep along in it, until you can find a better. I hazard the conjecture, that there is now about each of your establishments at home, some defect, or misarrangement over which your eye has wandered a thousand times without discovering it. Extend the remark to your farms, fences, tillage and stock; you will find enough to fix your attention, and put in requisition all your powers, be they what they may." * * * * *

"A competency—Neither poverty nor riches—is essential to our happiness; so essential, that he who is married without the possession or prospect of it, is a mad-man; and waving all courtesy, the girl that would marry him is a fool; and that as well whether he be in the possession of it with habits likely to dissipate it, as when he is without either the possession or prospect of it. There is no weighing, nor measuring, nor counting the calamities incident to a destitute and embarrassed condition. Thy

press upon the breast of a man like an incalculable weight; they obstruct the pulsation of his heart; they deaden the current of his life; they wither the beauties, with which nature would deck him by day and fancy beguile him by night; they are the ever present messenger of sorrow and evil tidings. And nothing but the reduction of a father to something less than human, or elevation of him to something more, can reach such a state supportable. It is, therefore, of the highest duties and ought to be inculcated from the cradle up, as well upon those who are born to a competency, to maintain, as upon those who are not, to acquire it; for it is favorable to the growth of all the virtues and essentially domestic comfort. It is the little vase of earth in which your flowers and shrubs, that ornament and embalm your fire sides and sweeten and cheer the intercourse and sympathies of husband, wife and children, are to grow and flourish. Is it not then worth a little self-denial, the doffing of an extra ribbon, and another effort to accomplish it? Tell ye who can recollect enough of the trifles we have thrown away as of nameless import and for which you were not a whit the better, to wrap your children warm in flannel, to light a cheerful fire in your own neat and comfortable dwellings, to spread your table with abundance of wholesome food, and to cheer you, if with the prospect that these blessings will continue and brighten upon you, without the aid at least without the reproof, of charity,—me, is it not worth an effort?

"You recollect, that without extraordinary talent, industry or economy, we have not more to expect than a living. While there I have only time to urge you to improve without dwelling upon the means; and to double your diligence, without noticing where we are remiss; I will detain you for a moment if you please, upon the subject of Economy within your houses; economy in buying them; and economy in one other particular.

"Economy is to industry, what the measure is to the mind—it retains for use. The great secret of making estates, lies in this. You only to apply your arithmetic to the operation compound interest, during a moderately long life, to be satisfied of this fact. A dollar expended at twenty-one, does not accurately devalue the extent of your loss. You not only lose a dollar, but you lose many more, which will subjecting you to any trouble, it would I earned you. You grub up the measure of wheat which is well sown, and in a good and which would yield you, not merely one an annual, and a perpetually increasing crop. Extend the application of this remark to your expenses for dress, furniture and equipage, indeed to your business and methods of conducting it, you will find various particulars in which savings may be made, trifling in themselves, admit, but in their results, wealth. Throw a few ten dollar hats, ye who have your estates to make and who would vault the stars with wing or trumpet; throw in a few pair of dollar boots; a few watches—a most abundant article!—to say nothing of their appendages, indications, which have involved in such uncertainty, the business of metallic research—in a few other superfluous commodities, if a gallery will permit, and if not, throw them

you will have a collection directly, which, without any other magic than that of a little patience, will make you an estate.

"However, it is more to my purpose to suggest, that negligence, in the department of a house-wife, will either make, or keep, her husband poor. No providence nor exertions of a man can sustain his family and improve their condition, against this silent and ceaseless corrosion at the heart. It is the perpetual dropping, that will wear the marble and exhaust a sea-man, therefore, has a slatternly wife, it is over with him. The weird sisters may and up his destiny as soon as they please.

"Entering upon life, a young man, with something before hand, builds a large house. It is to be furnished. By this time, all he is worth and his wife too and perhaps something more, is invested in it. Fences and out-buildings correspond. Repairs must be made as occasion may require. Taxes must be paid. Furniture replenished as fashion varies. And, with a fine establishment, there would be no resisting the temptation to shew it frequently to one's friends. Now I affirm, that at the age of fifty, if instead of building, he had hired, or rented his accommodations strictly to his needs, the capital he would have saved and profit upon that capital, would have amounted to a handsome estate. But suppose he been able to maintain and educate his family.

When he makes his will, he gives his estate to his favorite son, and, to make his children equal, charges him with the payment of legacies to the others. Thus the son befalls, with an accumulation of debt upon him, and, in the issue, sinks under it. Go where you will, the eye meets with a succession of large houses, in every stage of dilapidation from broken windows, to falling sheds, to prostrate walls. And, what is singularly characteristic, we build for the summer; so in order to keep cool, one third of the year, we have full employment, the other two thirds, to keep warm. A different practice would have put a new face upon New England, who would live in a little hutch of a place! There is a general objection, and away goes all a man's philosophy on the subject.

The other particular, upon which I promise a remark, although too important to be passed in silence, yet, as it has been the subject of complaint by my predecessors, I shall be excused.

"I only notice; for, if the certain consequence of ruin to health, to character, to fortune to family, and, if you choose to look beyond the career of ruin onward; if to a man, admits the truth of these realities, and feels too, and with a sensibility that maddens to mortal torture, and deepens to anticipated hell, the living images appeal in vain, what think words can do! Oh, there is not in nature, an object more to be commiserated, than an inebriate man, thus bound down and chained to his destiny by this tyrant habit. He is in the position of Laocoon, in the folds of two enormous serpents; and what heightens the horror of the conception and finishes the analogy, the complicated wreaths of the strong and poisonous and resistless monsters that wring their way to death—embrace his children also. Is it an object worthy of this society, of the united effort of this society, to see if something cannot be done to stay the progress of

this appalling evil? If you cannot extinguish the fire, may you not countermines and counteract it, so that when the materials upon which it feeds are consumed, it shall go out? But at present, it is bursting every barrier and kindling along the whole line of life."

* * * * *

"You patronize household manufactures and encourage them by your rewards. You do right. But upon what principle is it, that the labor of a girl, that turns a single spindle, can be productive, and the labor of another, that turns one hundred, the reverse? There is the expense of the machinery! True, and there is the saving of the wages and board of ninety-nine persons. And not only so; while the labor of one hundred persons is thus despatched by one, the ninety-nine are all at liberty, and each of them can do as much work, in the same way, as the individual spinster. If the one deserves patronage, therefore, I leave it for you to determine, whether the other is not entitled to protection? But the master of a family, if he cannot sell, can consume; the manufacturer, however, must sell, or his business must cease. And, therefore, a wise government will enable him to do it,—not for his own sake merely, but for the good of the great fraternity; or, if you please, of the family.

"The balance of trade, as it respects England, is against us; but the conclusion, that therefore it is a losing trade, is denied. Without stopping to trace the arguments in their windings, or contending that the custom-house returns indicate the exact truth on this subject, or controverting the position, that it does not follow, *of course*, that it is a losing trade; yet it is quite apparent that an individual may purchase and consume more than he can pay for. A nation may do the same. And an individual does it, when the amount of his purchases and consumption, for a given time, exceeds the spare product of his industry and capital, supposed to constitute his means, for the same time. A nation does it, under like circumstances. When an individual mortgages his estate, or parts with vested and productive property, to the trader, his condition is obvious. What means then, permit me to inquire, the almost unlimited transmission of stock, both bank and national, to England? When the day of reckoning and payment comes, let the guardians of the public credit look to it, that its pillars do not tremble.

"It is not two hundred years since Great Britain imported her broadcloths from Belgium, and not one hundred since she derived her cotton goods from Germany. Had she acted upon the principles which we oppose, she would not have sold a yard of either, even in her own market, to this time, while now she supplies half the world with both. But, instead of leaving manufactures to originate and protect themselves, she originated them by prohibition and protecting duties. In the time of Elizabeth, we find the great Bacon, vehement, in protesting against the importation of foreign products, on account of the national dependence and poverty which it involved. To this day, the ports of Great Britain are closed against the introduction of a single manufactured article, which British industry and British capital can make. No sooner did our straw-braid find its way into London, than a petition went to Parliament for an act of exclu-

sion. "Suppose the tables reversed and that we could undersell Great Britain, in her own market. Would she permit it? She would sacrifice her manufacturing capital, it will be said I say more. She would not only sacrifice that, but her agricultural capital with it.

"Increase of population and consequent demand for produce, originally gave, and still give, value to land. How injurious, therefore, to New England has been the emigration to the westward! The magic that has reared the towns and villages in that part of the country, has been your citizens and your capital, under the double influence of increased exertion and increased economy, the prevalent virtues of a new settlement. I know that politically, some advantages may accrue from a New England population there, and I by no means wish ill to those of our friends who are interested in the lands there, but, to the same extent as emigration prevails, the value of property is reduced here, to say nothing of the loss of capital and of men—the most valuable of all capital. It is this, among other causes, that has left farms upon the hills without tenants, without purchasers, and without price. Bleeding at every vein, for a succession of years will reduce any subject to depletion. The way to restore health and soundness, in such a case, is to cut the ligatures and staunch the blood.

"The bounties of Providence are distributed with more impartiality than we imagine. Wherever a privilege is given, or hardship imposed, an equivalent is exacted, or conferred. Our hills are rough; but the business of grazing affords leisure to farmers, for the very purpose of enabling them to subdue the rebellious character of the soil. Our river lands are productive; but the price of them is comparatively high, and without yielding to the proprietor a better return than the hills for the interest of his money, they exact of him more labor. With industry and economy, the necessity of which is a blessing, we can all live, and in the Arcadia of the western world, they are not exempt from the common lot. At certain points of remove, deformities disappear in the indistinctness, or blend in the light, of the landscape. For more reasons than I have time to assign. NEW ENGLAND is the place in which to live and to die."

(To be continued.)

Vaccination.—The following incident, says the Norfolk Herald, while it serves to shew the brutal prejudice which still prevails against vaccination, is another among millions of proofs already adduced, of its efficacy as a remedy against the Small Pox. The incident occurred in France, and is recorded in the *Gazette de Santé*, (Gazette of Health) of Paris. A woman in a village near Cherbourg, mother of 4 children, had the good sense and courage to have her young family vaccinated. After some time the Small Pox made its appearance in the village. All the children, excepting the four vaccinated, were infected, and many died. The women who had mocked at the wise precaution of the happy mother, mortified at her security and comfort, enticed the children to their houses, and smeared their faces with variolous matter. Their malignity was only further embittered by seeing that all their efforts to communicate the disease to the vaccinated children were unsuccessful.

To the Editor of the (London) Farmer's Journal.
ON STORING MANGEL WURTZEL.

SIR,—Lest your correspondent's letter in this week's Journal on Mangel Wurtzel should mislead the growers of that root, by stating that it will stand the frost, I would beg leave to caution them against trying the experiment, lest they should meet with a serious loss. If they are a good crop and well covered with tops, I believe they will stand the frost as well as our common white turnips. Some gentlemen in this part of Norfolk, about seven or eight years since, grew a fine crop; they were valued by a surveyor at £12 per acre, and the turnips on the same farms at three or four pounds. They were advised to take them up and store them for spring feed: their mode of doing it was, all the tops were taken off, the roots were then taken from the ground, and left in small heaps to be carted home when a convenient opportunity offered; a sharp frost caught them in that situation in the end of November, and destroyed their whole crop to the amount of several acres: this made them so angry that I believe not one of them have grown any since. Many acres have since that time been grown near them and much approved of. I have some roots now by me very sound and good, that were planted in July, 1822, after my hay was taken off: the rows, three feet apart, were covered up by the plough in autumn, and remained there all winter. I had also some that were not mounded up, but had a heavy crop of tops that stood till the spring, although the winter was very severe, but these were eaten off by my cows as soon as the frost broke up, or I believe they would have rotted very soon. If our common white turnips were topped and taken from the ground, a slight frost would destroy them as soon as it would the mangel wurtzel; for that part of the root that grows in the ground is very tender and susceptible to the frost. I store the greater part of mine. We take no more tops off than we cart roots to the heap in the day, commencing as early in November as we can. Two carts, three horses, six or eight women or youths to load, and a man to drive them to the heap, will remove a great many in a day. The driver shoots them out of the end of the cart, or tumbril, in a promiscuous way, on as high a heap as he can, about two loads deep, on the level ground in some sheltered situation: he continues to add to that heap in the same way he began, till he has got as long a ridge as he wants; the scattered ones are then thrown upon the top of the heap to as sharp a point as they can conveniently be laid; as much straw must then be scattered over them as will prevent the mould from mixing with them. The ground round the heap, with the carts, and treading of the horses, is pressed so close as to be difficult to dig. I plough as many deep furrows round the heap as I want mould to cover it about six or seven inches; it is then harrowed and rolled till fine, then ploughed a second time, beginning each time next the heap; by this means the mould is brought to it, and in its fine state is easily cast over them with a shovel, for the lighter and finer the mould is the better it will resist the frost. I prefer this method to putting them into a hole, as the practice is with some, because the waters are carried from the heap into the trench; in the latter case they fall into the trench amongst the roots: I have preserved

them good till after Midsummer, and have found them useful for stock in a dry season, when the grasses fail. The ground cleared at this time is ready for sowing wheat, or to be ploughed, and remain the winter for a spring crop. I have seen heavy crops of barley where the tops have been ploughed in, but I prefer giving them to the stock, as they eat them with avidity. My people are now reaping wheat that was sown after the mangel wurtzels were taken off last November; it is laid at twelve coombs per acre. Your *Surry Correspondent*, in a recent letter in your Journal, is very much mistaken respecting the fattening qualities of the mangel wurtzel. I heard a respectable grazier state, in a public market, that he made a quantity of beasts fat this last spring with these roots in the shortest time he ever saw any fatted before with any thing. I have some friends who have regularly fatted beasts for the London market several years, who all concur in the same opinion. I feed my cows, horses, and pigs with them, and find them very nutritious. I am, Sir, your's respectfully.

THOS. HEROD.

From the American Farmer.

GLANDERS IN HORSES.

Dounington, 12mo. 19th, 1823.

ESTEEMED FRIEND,

I have noticed in the last Farmer, a proposal to send thy subscribers one half sheet with advertisements, and an almanack in the fall; which I think I may be safe in saying, will be a gratuitous addition to all those who estimate the present value of thy paper properly.

I have also noticed a request made by Robert Lowry, in the last Farmer, for information respecting the glanders; to whom I feel willing to give my small experience, or do any thing in my power for the preservation of so useful an animal.

I have in all the cases that have come within my knowledge, uniformly traced them back to what is here termed the distemper, and by some the stranglers.

I consider the glanders to be a neglected or violent case of the distemper: from a repeated discharge from the nose, and constant inflammation, the glands become ulcerated, and finally the smaller bones of the nose become carious, and of course incurable, as they are not so situated, as to admit of an operation being performed on them; in this stage the horse has been inoculated, mercury has been tried, and both without success.

But take the distemper, or stranglers, in time, cure it effectually and you prevent the glanders.

SYMPTOMS.

The first thing discovered is a rattling in the throat, with dulness of countenance, apparent drowsiness, and some fever, then a swelling in the throat and between the jaws, a discharge at the nose, and sometimes cough; if the horse does not die by the swelling at his throat, it becomes what is called glanders.

CURE.

Dissolve one pound of glauher salts in warm water, set it in a bucket in his manger, and he will drink it; take half a gallon of blood from his neck vein; give a mash of two quarts of wheat bran scalded with sassafras tea, after which offer him lukewarm water to drink, and do not suffer him to drink any other kind for

that day, next morning take the same quantity of blood as before, give a mash as before, with the addition of half an ounce of salt petre dissolved in it, let his food be wet, and of a w. kind—a run at grass after the first two days would be of service.

If thee thinks this prevention better than cure, thee may give it a place in thy paper.

Respectfully thine,
JOSEPH KERSEY

From the Newburyport Herald.

Good Cider.—Year before last, I made an experiment on two barrels of new Cider;—in of which I put a gallon 4th proof Cognac Brandy, which cost \$1.75 per gall.; a peck of dried Shagbarks, with 3 lbs. of box Raisins. The other barrel, I put 1 gallon Cider Brandy which cost 50 cts. These two barrels I in my cellar, alongside of each other, but perfectly tight, and free from air, and let it remain one year. When I tapped the first, I scilicet with the Cognac Brandy, &c. in it, I found to my surprise and mortification, it was a shade better than common flat Cider, with tart, disagreeable taste, approaching nearest common vinegar than any thing else. The other barrel with the Cider Brandy in it, I found to be of the first rate quality, resembling pith of frozen cider. I showed some of this to a friend, and he pronounced it of the quality without doubt; and to corroborate opinion of it, offered me \$6 for the barrel of cider.

If our tavern keepers, and others, would adopt this method, I am confident it would do away the impression which too many travellers entertain, that no good Cider can be found in the best part of New England. EXPERIENCE.

POWER OF MACHINERY.

The Philadelphia papers notice the invention of a machine, with double heads and three rollers, by which the inventor proposes to perform the operation of drawing cotton in a more perfect manner, with less labor, and a simplified and less expensive machinery by the present mode. The rapidity of the improvements in the art of cotton spinning has been, within a few years been a matter of surprise. Mr. Owen, the proprietor of the extensive works at Lanark, in Scotland, calculates that two hundred arms with machines now manufactured as much cotton as twenty million hands were able to manufacture without spindles, forty years ago; and that cotton now manufactured in the course of one year in Great Britain, would require without machines, ten millions of workmen, with simple wheels. He calculates farther that the quantity of manufactures of all sorts, at present produced by British workmen, with the aid of machines, is great that it would require, without the aid of machinery, the labor of four hundred millions of workmen. At some of the cotton mills in Manchester, yarn has been spun so fast as to require 350 hands to weigh one pound avoirdupois. The perimeter of the cotton reel being one yard and a half, 80 three revolutions would measure 120 yards and a half seven times as much; or 840 yards multiplied by 350 gives 294,000 yards, or 167 miles and a fraction. Connected with this subject may here introduce the following history of the pound weight of manufactured cotton as shown

the importance of the trade to England in a very conspicuous manner:—The wool came from the East Indies to London; from London it went to Lancashire, where it was manufactured into yarn, from Manchester it was sent to Paisley, where it was woven. It was next sent to Ayrshire, where it was tanned; afterwards it was conveyed to Dunbarton, where it was handwoven, and again forwarded to Paisley, when it was sent to a distant part of Renfrew to be bleached and returned to Paisley, where it was sent to Glasgow and there finished; from Glasgow it was forwarded by coach to London. It was difficult to ascertain precisely the time taken to bring this article to market; but it may be pretty near the truth to reckon it three years from the time it was packed in India till it cloth arrived at the Merchants Warehouse in London; whither it must have been conveyed 5000 miles by sea, and 920 by land, and contributed to reward no less than 150 people, whose services were necessary in the carriage and manufactures of this small quantity of cotton, and by which the value was increased 2000 per cent. [N. Y. Evening Post.

Small Pox.—It is reproachful to the intelligence and prudence of the people of New-England, that this fatal disease should now find victims among them. Vaccination affords protection from the small pox, as certain as any danger which human precaution can in any case provide. To doubt its efficacy is to be sceptical where there is evidence greater than is usually deemed requisite for the government of conduct. Who hears of the ravages of this disease among those who have been vaccinated? In some countries of Europe—we believe it is so in Denmark—no individual can hold any office, or be admitted into any school, who has not a certificate having had the kine pock. The consequence is, that the small pox is not known. The Boston Patriot suggests that some measures ought to be adopted by our Legislature, to produce the same result. We heartily concur in this suggestion.

Until, however, some Legislative act be passed on the subject, it must depend upon individual influence and exertion to diffuse the means of guarding the community from a loathsome and fatal contagion, and to induce the people to esport to them.

We have been led to these remarks in consequence of noticing that in several towns in New-England, the small pox has been recently introduced from New-York, producing its usual alarming effects. What town in this County is free from the danger of this contagion? Probably not one. A few years since, vaccination was very general; but of late it has been neglected. Probably three fourths of those in this County, under ten years of age, are liable to the small pox.

We cannot but urge, therefore, upon physicians, as they regard the welfare of the community, and upon heads of families, as they feel the weight of the obligations resting upon them, the importance of an immediate attention to the means of guarding against this contagion. Let every parent and master see to it that his family are vaccinated, and individuals of influence exert themselves to impress upon their neighbors the importance of the measure.—Mass. Yeoman.

From the Connecticut Journal.

MR. CONVERSE.—Most of your readers are undoubtedly acquainted with the difficulty of removing grease spots from clothing, without injuring the cloth or mixing the colors. For some time past, I have been in the habit of using highly rectified Alcohol, and with so much satisfaction, that I am induced to hand you this communication. I am well aware it is not new to all; but to the generality of the community I am persuaded it cannot be known; otherwise they would not be so ready, with the turpentine bottle, to clear one spot by covering it with another, a good deal deeper and broader. My mode of using the alcohol is this,—a small piece of sponge is wet with it, and rubbed upon the spot very thoroughly, until nothing can be seen, and the cloth nearly dry. I have in this way taken out grease spots from various kinds of silk, from cloaks, from carpets, from the collars of coats, &c. I am not prepared to say that this will answer in every possible case; but if the alcohol be good, and the application judiciously made, the instances of failure will be comparatively rare. When the garment can be washed, good soap and soft water will uniformly succeed in common grease or oil spots; but if any resin or wax be present, alcohol is indispensable.

Economy.—The following is the result of an experiment, actually made in order to ascertain the comparative expense of oil and candles. An ordinary Glass Lamp, with a wick half an inch in breadth, was placed beside a mould candle, of the size called sixes, and both allowed to burn 16½ hours without being moved. In that period of time two candles and three-fifths were consumed, and a fraction less than one third of a pint of oil. (A pint weighing 15½ ounces, and the quantity consumed was 5 ounces.)

From this experiment, it appears that one gallon of oil will burn 402 hours and 3-5, and that it requires 10 and 3-5 pound candles, to burn the same time, so that supposing oil to be 75 cents per gallon, it will be equal in expense to mould candles at 7 cents per pound.

As oil may be purchased for less than 75 cts. and in the ordinary use of candles there is a considerable waste from their being moved, it is evident that the advantages on the side of oil are very great. A HOUSEKEEPER.

Editor's Correspondence.

FISH FOOD FOR SHEEP.

A friend in Maine writes to us as follows:—"I made a communication a few years ago to the Eastern Argus on the subject of feeding sheep with Fish. Whether it was of any use I know not, except that it afforded occasion for an Albany Editor of a Newspaper to display his wit, by enquiring "how the sheep would pick out the bones?" It is, however, a fact, important to those who are situated where large quantities of any kind of fish can be obtained, that sheep will devour them greedily, either pickled, dried in the sun, or smoke if they are only well salted. Judge Lincoln, the greatest, and most scientific farmer in this [Washington] County, first mentioned it to me. He always places as many dry alewives before his sheep as they will eat.—

They require but little hay, and are always in fine order.

THRESHING FLOOR.

The same gentleman says, "I have seen accounts of *Threshing Machines*, which have been highly recommended, but never have seen one in operation. I apprehend, however, that under every degree of improvement they will be too expensive ever to be generally used. Great farmers will use them, but smaller ones will still be obliged "to get their bread by the sweat of their brow." For the benefit of such I have a project for an improved *Threshing Floor*. I consider that the labor of threshing is greatly increased by the accumulation of grain on the floor, which diminishes the effect of the strokes of the flail and renders it necessary frequently to remove the straw, and rake out the heads from the grain and put it aside. My plan is to lay a second floor, six inches or more above the permanent one. I would place two sticks of timber, one on each side of the barn floor, cut dry planks of suitable length, and lay the ends on the timbers. Set them close together, and fasten the two outside ones with pins. Then, in that part of the floor, where the heads of the sheaves would be placed, I would bore a sufficient number of holes, with an augur of about three fourths of an inch diameter, as would let the grain fall through, taking care to make the holes smooth. Should the floor be found to spring too much, while threshing, another piece of timber might be put under the middle; but not quite so large as the others, that the grain might incline to the centre. A very simple instrument might serve to shell out the grain, which would be free from the heads, ready for winnowing. The floor may be easily taken up and laid aside till wanted again. The extent one way should conform to the width of the permanent floor, and it might be extended the other way to accommodate one or two threshers as should be found convenient. For threshing peas or beans, such a floor must be much the best, as they would be less liable to be bruised.

Your friend, &c.

ARM. BUTTERFIELD.

Michias, Me. Jan. 12, 1824.

MR. EDITOR.—The following instance of instinct or natural affection of a young hen, may perhaps be interesting to some who rear domestic fowls.
